AN INDEX OF PROGNOSIS

AND END-RESULTS OF TREATMENT

Edited by A RENDLE SHORT, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng.,
Hon. Surgeon Bristol Royal Infirmary

IN CONJUNCTION WITH 27 SPECIAL CONTRIBUTORS

Sets forth the results and particularly the end results of various methods of treatment in such a form as will enable the practitioner to obtain a fair unbiased reasoned opinion as to the prospects of securing for his patient permanent relief and the risks of such treatment. It also furnishes data by means of which apart from the question of treatment one may arrive at an accurate forecast of what will probably happen to the individual patient.

To-day when methods of treatment have multiplied it is more than ever desirable that the doctor whether he be general practitioner or specialist should have some such guidance as this so that he may choose the better and refuse the worse.

We have formed a high opinion of the value of the Index of Prognosis and desire to commend the work to our readers as one which they would do well to place upon their bookshelves.—BRITISH MEDICAL JOURNAL.

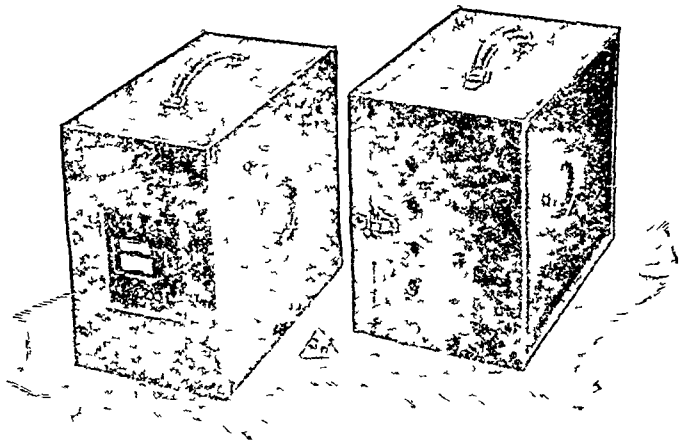
Education and Endowment

To Parents—

You desire, naturally, that your children shall receive a good sound education to fit them for life among their fellows

Education costs a lot of money—quite a lot—and the future may be uncertain Let us tell you how the cost can be met by provision under an Educational Endowment Assurance Even should you die the moneys required will still be forthcoming

Then, you ought to do something more for him or for her You want to make sure they can have Life Assurance when they grow up.



At a cost of £10 a year you can secure for them quite a nice policy on their coming-of-age, giving them protection even should they not then be first-class lives—and so otherwise uninsurable

You may do even more, you may help the Guild to educate the children of people who are less provident and far-sighted than yourselves—at no cost to yourself.

The Medical Insurance Agency will be pleased to tell you all about these schemes if you will send a note of your own age and the ages of the children (next birthday) to —

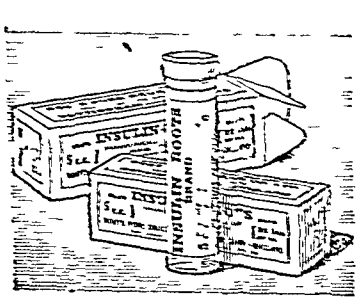
THE BRITISH DRUG HOUSES LTD. LONDON N.1

INSULIN (BOOTS)

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd. under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.



It is made from selected ox pancreas which is subject to the strictest examination before use.

The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out.

Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. A sample of each batch together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

It is Wise to Add Wright's when prescribing "Liquor Carbonis Detergens"

Although there is no secrecy as to the composition of *Liquor Carbonis Detergens* (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion usually accompanied by some primitive percolation and inadequate stirring, whereas, in the case of the genuine product the intimate contact required for the complete extraction of all the soluble antiseptic constituents is attained by a series of complicated processes, involving the use of highly specialized machinery.

INSULIN 'A.B.'

The world-wide supremacy of Insulin 'A.B' is due to its unequivocal purity no less than to its well-known potency and stability under all conditions.

Insulin 'A.B' contains the minute quantity of phenolic preservative originally recommended by the Medical Research Council and still considered necessary by bacteriologists (*Lancet* Sept. 12 1931 pp 582-584) as a complete safeguard against the development of bacteria that may be accidentally introduced during self-administration

Supplied in three strengths
20, 40 and 80 units per c.c.

Full particulars and the latest literature will be sent free to members of the Medical Profession

An Improved form of Treatment for Digestive Disorders

'Alocol' is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate or bismuth; furthermore 'Alocol' eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When 'Alocol' reaches the stomach adsorption takes place, a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

Alocol is highly recommended for use in all cases of hyperacidity against which it is a specific. It is also indicated in the more serious manifestations such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of Alocol with continuing clinical reports and supply for trial sent free to physicians on request

A. WANDER, Ltd., Manufacturing Chemists, 184 Queen's Gate, London, S.W.7

Works: KING'S LANGLEY, HERTFORDSHIRE

M233

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

Alasil completely overcomes this objection. By combining calcium acetyl salicylate with Alocol unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of Alocol (Colloidol Hydroxide of Aluminium) which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. Alasil is therefore a triumph over acetyl salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative. Alasil is indicated in all cases where acetyl salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request

A. WANDER, Ltd., Manufacturing Chemists,
184 Queen's Gate, London, S.W.7

M 235

HORLICK'S MALTED MILK

A VALUABLE ADDITION to a diet at any time—especially so during the winter months. At this season of the year, the lack of stamina and diminished resistance to infection so closely related to errors in nutrition most conspicuously manifest themselves. It is therefore, all the more necessary that care should be taken to ensure that patients shall be given a diet which will satisfy their energy needs, lessen fatigue, prevent tissue waste and build up a reserve. HORLICKS a well-balanced food with its easily digested protein, its readily assimilated fat and mixed carbohydrate—lactose, maltose and dextrin and adequate vitamin content promotes physical and mental fitness, increases resistance to infection and restores vitality. To combat Influenza, Pneumonia and other complaints so common in winter HORLICKS can be prescribed with confidence.

The perfect

LOCAL ANAESTHETIC

at last . . .

SELF STERILISING. Novutox Local Anaesthetic is autogenously sterile and actually remains sterile for weeks after an ampoule or bottle is opened. Novutox can be stored in and used direct from a bottle, thus eliminating waste and economising both time and money.

• • • NOVUTOX BRAND LOCAL ANAESTHETIC can be safely injected into infected infiltrated areas.

BETTER MILK FOR BABIES

FACTS ABOUT LACTOGEN

Vitamins and Minerals

To fulfil the requirements of the rapidly growing child an adequate supply of vitamins and mineral salts must be provided

Milk furnishes a sufficiency of these essentials, and in Lactogen their complete conservation is effected

For the final desiccation of the modified fresh milk the roller process is employed The heat applied is thus reduced to a minimum and the exposure confined to a matter of seconds

Lactogen provides a full complement of mineral salts in organic combination, together with the adequate vitamin allowance It is a complete and balanced diet furnishing the infant with every essential necessary for good health and normal development

Lactogen is neither a new nor untried product First introduced in Australia, it has for many years enjoyed a large sale in overseas countries

The most satisfactory form in which to administer Petroleum

Liquid Paraffin is repugnant to many fastidious patients because of its oily, greasy character Occasionally it causes nausea and upsets the stomach Frequently there is leakage which prohibits its continuous use Even when taken readily and without these drawbacks, its failure to mingle with the food and with the fecal mass, lessens its full efficacy

Angier's Emulsion is made with a specially purified petroleum of just the right degree of viscosity It is palatable and freely taken by those who object to the plain oil, it does not nauseate or upset the stomach, it is readily miscible with water or milk; it mixes with the feces, keeping them soft and plastic and ensuring maximum lubrication, the characteristic action of petroleum is obtained with greater uniformity More over *Angier's Emulsion aids Digestion and facilitates Assimilation*

Thirty nine years of clinical experience have demonstrated the foregoing so conclusively that countless physicians now look upon Angier's Emulsion as the most satisfactory and effective form in which to employ pure petroleum

A natural

COD LIVER OIL CONCENTRATE

containing both vitamins

A *and* D

in a pleasant tablet form

The Vitamin A and D in each tablet is derived entirely from the pure cream separated from the finest Pure Cod Liver Oil. The fish in the oil are of the richest kind, the livers being obtained from deep-sea fish caught in the Arctic.

White's Cod Liver Oil Concentrate represents 70 c.c. of the finest oil. Each tablet contains at least 700 International units of vitamin A and at least 50 International units of vitamin D, these values being determined by the MacCallum Last Test, which is the most reliable method of assaying Cod Liver Oil.

White's Cod Liver Oil Concentrate is a concentrate of the vitamin potency of the finest oil, and not of the oil itself, so that the bulk is greatly reduced. It is small and easy to take, and the oil, great nourisher and restorer of health, is presented in its most digestible form.

Indications—Tuberculosis, Rickets, Anæmia, Malnutrition, Infantile Weakness, Dyspepsia, Debility, Nervous Disease, Wasting Disease, Respiratory Diseases, and all Weakness.

One or more COD-LIVER OIL tablets to be taken.

Unlike ordinary cheap tablets, contain no gum or other extraneous binding matter and therefore cause no nausea or flatulence. White's Concentrated Cod-Liver Oil Tablets are extremely palatable and being of small size, may be easily administered to infants, one tablet being equal to one B.P. dose of Cod-Liver Oil for a child.

Every purchaser is entitled to Cod-Liver Oil Medicine Chart and to consult with our Clinical Staff free of charge.

PRESCRIPTIONS FROM AN ANGLO-SAXON MEDICAL MANUSCRIPT THE EARLIEST EXISTING EVIDENCE OF AN AWAKENING OF THE TEUTONIC MIND TO SCIENTIFIC THOUGHT —The Anglo-Saxons in England developed an eager spirit of enquiry towards the healing art—a new departure among the Teutons. The Anglo-Saxon physicians compiled a number of Leech-Books some of which have come down to us. It is not claimed that they discovered or invented anything of value in the domain of disease and medicine but they were real pioneers in the sense that they did begin to study their subject, to seek information from whatever literary

sources were open to them and to qualify themselves for their profession the existence of these books is evidence that leeches did exist and that they committed information to their own tongue. The Leech-Book of Bald and Cild is a mixture of folk-medicine pure Christianised of remedies drawn from the Later Greek medical authors and a small number of prescriptions taught by native Anglo-Saxon leeches. The treatment for 'Alf' (i.e., corpse) a portion of which is here reproduced, reads 'Work thus a drink against dust Take mugwort, seethe it in a copper kettle and boil it till it be very thick and let it be brought of fourteen mill-dust of everfern moss, bishop-wort, water agrimony pennyroyal, sagewort, set all in a vat, give to drink at the midday and forego sour and everything sick.'

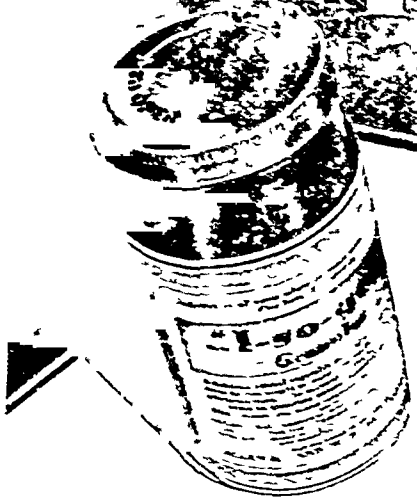
WHOOPING COUGH

Whooping Cough is a condition in which treatment with a suitable vaccine has proved remarkably successful Some Practitioners, however, are deterred from using Vaccines, owing to fear of reactions, but this objection may be overcome by employing Detoxicated Whooping Cough Vaccine (Genatosan) In the preparation of this vaccine all the toxic elements of the germ are removed, as a result it is given to young children and infants without any harmful reaction and produces a high degree of immunity

The following extract from a Practitioner's letter may prove of interest —

" . Some time ago, I resolved to try for the first time a vaccine in whooping cough and the results were so excellent, that I thought you would be interested to hear from me



(*a*) Three children aged 3 years, 2 years and 8 months, were treated when the disease was about 10 days established, all were completely cured after the third injection—the mother described the effect to me as simply miraculous

(*b*) Two aged 6 years and $3\frac{1}{4}$ years, who had relapses, were well after they had got the 2nd injection

(*c*) An infant aged 8 months—the whoop disappeared after 1st injection The cough was gone after 2nd injection, and the mother, who had tried everything and despaired of the child's life, was exceedingly grateful and assured me it was simply wonderful to see how the child had slept for the first time for days and was able to retain its food and rapidly put on weight The Vaccine used was your Detoxicated Whooping Cough Vaccine Speaking for myself, I can only describe the effects as magical, as the children were worn out and emaciated from coughing, vomiting, and loss of sleep "

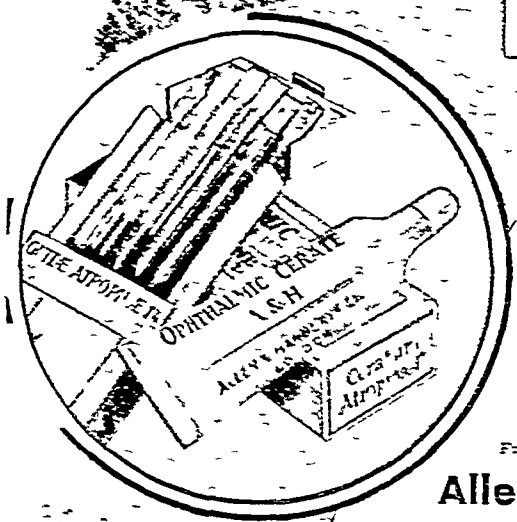
Additional information regarding the above Vaccine will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd, Loughborough, Leicestershire

"Iso-gel" Granules

Indicated in Chronic Constipation, Colitis, and allied intestinal disorders

"Iso-gel" is a natural vegetable material. The granules absorb many times their volume of water and swell into a gelatinous mass which both stimulates natural intestinal movements and soothes inflamed intestinal mucous membrane. Indicated in chronic constipation colitis and allied intestinal disorders. Action purely mechanical. Sugar-free. Ideal for diabetics

In bottles at 2/6 and - 6 each



Descriptive Literature sent post free on application

Allen & Hanburys Ltd., London, E.2

Trade Mark Registered and Trade Name "Graduary Bath Cream"

Ophthalmic Products

"A. & H."

Prepared in accordance with the latest scientific methods

Highest degree of activity and stability ensured

The series of Cerates and Drops comprises most of the agents used in everyday practice

Any special formula can be prepared

Further particulars and samples are obtainable from

Allen & Hanburys Ltd.

London, E.2

PRODUCTS OF THE GLAXO LABORATORIES

Ostelin vitamin D LIQUID

By means of Ostelin Liquid the practitioner can prescribe vitamin D in strictly controlled amounts It is a tasteless odourless glycerin suspension of irradiated ergosterol It is miscible with water It can be prescribed in mixtures

In 8 c c phials 2/6
Other sizes for dispensing

A guarantee of purity and biological potency

Every preparation that bears the Glaxo Laboratories device has been subjected at every stage of its manufacture to rigorous scientific and technical control

It has moreover been assayed by one or more of the most precise chemical or physiological methods available the results being expressed wherever possible in terms of recognised units

The G L Device

represents a pure biologically potent and accurately standardised preparation of the Glaxo Laboratories

GLAXO LABORATORIES, 56 Osnaburgh Street, LONDON, N W 1

Colloidal Calcium with Ostelin vitamin D

For children a School Medical Officer has described subcutaneous injection of Ostelin and Colloidal Calcium as a specific treatment. Extensive clinical tests have shown it to be equally valuable as a prophylactic

In boxes of six 1 c c ampoules 5
In 1 oz. bottles 10

ADEXOLIN CAPSULES

Vitamins A and D highly concentrated

In acute infections Adexolin brings the temperature and pulse rate down and enhances resistance It serves also to protect patients liable to frequently recurring colds influenza and to infections of the respiratory tract

Boxes of 25 Capsules 3/9 each
Boxes of 100 Capsules 12/6 each

ANTIVIRUS Preparations

Antivirin Brand

The results of antivirus therapy in several conditions are frequently described as remarkable

Full particulars with prices of the Antivirin series will be sent on request

Staphylococcus Antivirus
Streptococcus Antivirus
Staphylococcus and Streptococcus Mixed Antivirus
B Acnes Antivirus Ointment

OSTOMALT

Vitamins A B C and D—rigidly standardised—in a readily assimilable and appetising preparation A trustworthy supplementary source of vitamin C For convalescent or otherwise debilitated adults and children Ostomalt serves as an ideal tonic food stimulating the appetite for other kinds of nourishment

In ½ lb jars 2 6
In 1 lb jars 4/

GLUCOSE-D

A preparation of medicinal glucose in which is incorporated calcium glycerophosphate and vitamin D to assist a normal metabolism of calcium and phosphorus in conditions—notably acidosis asthma cyclical vomiting heart disease and fever—that may require both glucose therapy and the prolonged administration of a fat free and thence fat soluble vitamin free diet

In 1 lb tins—1 9

THE PROGNOSIS OF GASTRIC AND DUODENAL ULCER*

BY

LORD MOYNIHAN OF LEEDS P.R.C.S.

It is [illegible] with regard [illegible] aspects of those diseases which results we are now to discuss we have [illegible] knowledge of certain facts of each and [illegible] conclusion. We have [illegible] course drawn [illegible] the various clinical [illegible] we can form some estimate [illegible] and [illegible] probable [illegible] and [illegible] the stage at which [illegible] develop [illegible] and [illegible] in their [illegible] career. But we [illegible] [illegible] gastric or duodenal ulcer we do not know enough of their causation [illegible] are at present not [illegible] and very accurate records [illegible] the effects of medical [illegible]. We obtain glimpses [illegible] these diseases at various stages of their development but we lack complete biological knowledge of their causes career and termination. We may nevertheless find it useful to pass in review some of the facts gleaned from clinical inquiry from the operation theatre from pathological examinations and from the post-mortem room.

Acute Ulcers

In our discussion we must not altogether lose sight of acute and chronic ulcers. The former [illegible] are clinically important though [illegible] upon the matter some of the results [illegible] acute [illegible] of chronic ulcers are often classed as examples of acute primary ulceration.

Acute ulcers it would appear to be certain are the clear and grave evidence of systemic infections. On the post-mortem table as my colleague Professor Stewart has clearly shown such diseases as acute appendicitis gangrenous [illegible] empyema [illegible] meningitis [illegible] septicæmia acute endocarditis and middle-ear disease are not seldom found as causative agents in cases of acute ulceration. Less severe forms of infection derived from teeth—more extraction may show that a latent [illegible] streptococcus lies at the apex of the root—from tonsil and from various surface lesions such as burns are all held on clinical grounds to be responsible for severe attacks of hæmatemesis and melæna caused by acute ulcer. These ulcers affect the mucosa only and heal rapidly in favourable circumstances and leave no visible scar but they may have serious and even fatal consequences. In Professor Stewart's series of post-mortem examinations it was found that in 245 cases of acute gastric ulcer there were 21 cases of severe hæmorrhage 17 of them fatal (8 per cent.). In 11 of these no other fatal malady was found the acute ulcer being directly and solely responsible for the patient's death. In 88 cases of acute duodenal ulceration there were 6 cases of fatal hæmorrhage in these there was no disease other than the ulcer which could have caused death. It is clear therefore that hæmorrhage is a serious and sometimes fatal disaster in connexion with acute ulceration.

Perforation is also frequent in acute ulceration. In a period of ten years at Leeds there were 61 deaths following upon perforation of a gastric ulcer in one case only was the ulcer cancerous. In 117 deaths from perforation of a duodenal ulcer during the same period there were eight in which the ulcer was acute. Both hæmorrhage and perforation are far more commonly in chronic than in acute ulcer. The important point which requires emphasis is that acute ulceration is preventable if the infection which causes it can be prevented or quickly removed and experience shows that to be often possible if not almost always obtainable.

Chronic Ulcers

Acute ulcers are multiple chronic ulcers usually solitary. What is it that converts an acute into a chronic ulcer. There is little doubt I think that the chronic ulcer is often if not always the late result of the acute ulceration. There are perhaps many conditions which help to prevent the usually rapid healing of an acute ulcer. The acid condition of the gastric juice is doubtless an important factor especially in the production of duodenal ulcer. Approximately 72 per cent. of cases of chronic duodenal ulcer suffer from hyperchlorhydria. High acidity is infrequent in cases of gastric ulcer. In my own cases the results of Rehfuss tests are shown in the following table:

	Gastric Ulcer	Duodenal Ulcer
	Per cent.	Per cent.
Achylia gastrica	13·1	5·5
Hypochlorhydria	43·7	7·1
Low normal	19·1	12·3
Normal	3·2	5·5
High normal	18·7	24·2
Hyperchlorhydria	2·1	45·5
	29·8	69·7

There is clearly as Hurst has indicated an ulcer diathesis—especially I think a duodenal ulcer diathesis—a hyposthenic type. In patients suffering from chronic duodenal ulceration there is generally a high acid content of the gastric juice they are men of vigour strength athletic habits and often some prowess. I have operated upon international football players cricketers lacrosse players and great runners suffering from duodenal ulcer. Such patients are often found to have small highly placed stomachs which contract eagerly and empty rapidly and the acid content of the gastric juice may be such that the ordinary chart cannot record it. Many years ago I called attention to spasm in the stomach of such degree as to produce the appearance of tumour. As soon as an ulcer involves the muscular coat spasm is aroused it is often considerable and in the stomach is always local—that is it is throughout confined to the same zone. When seen by the radiologists a notch is observed in the greater

A Lecture
ON
THE PROGNOSIS OF GASTRIC AND DUODENAL ULCER*
BY
LORD MOYNIHAN OF LEEDS P R C S

It is unfortunate that with regard to many of the aspects of those diseases whose results we are now to discuss we have not the knowledge to enable us to reach an accurate conclusion. We are of course thoroughly familiar with their various clinical characteristics we can form some estimate of their etiology and are unhappily only too familiar with the tragedies which develop so swiftly and so mercilessly in their career. But we know little or nothing of the real frequency of gastric or duodenal ulcer we do not know enough of their causation to prevent them nor are there any very accurate records of the effects of medical treatment. We obtain glimpses of these diseases at various stages of their development but we lack complete biological knowledge of their causes career and termination. We may nevertheless find it useful to pass in review some of the truths gleaned from clinical inquiry from the operation theatre from radiological examinations and from the post-mortem room.

Acute Ulcers

In our discussion we must not fail to distinguish between acute and chronic ulcers. The former too are clinically important though confusion upon this matter sometimes results for the acute terminations of chronic ulcers are often classified as examples of acute primary ulceration.

Acute ulcers it would appear to be certain are the clear and grave evidence of systemic infections. On the post-mortem table as my colleague Professor Stewart has clearly shown such diseases as acute appendicitis general peritonitis empyema pneumonia meningitis puerperal sepsis acute endocarditis and middle-ear disease are not seldom found as causative agents in cases of acute ulceration. Less severe forms of infection derived from teeth—whose extraction may show that a haemolytic streptococcus has set up the mischief—from the tonsil and from various surface lesions such as burns are all held on clinical grounds to be responsible for severe attacks of haematemesis and melaena caused by acute ulcers. These ulcers affect the mucosa only but rapidly in favourable circumstances and leave no visible scar but in others may have serious and even fatal consequences. In Professor Stewart's series of post-mortem examinations it was found that in 2·5 cases of acute gastric ulcer there were 21 cases of severe haemorrhage 17 of them fatal (81 per cent.) in 11 of these no other fatal malady was found the acute ulcer being deemed responsible for the patient's death. In 98 cases of acute duodenal ulceration there were 6 cases of fatal haemorrhage in three there was no disease other than the ulcer which could have caused death. It is clear therefore that haemorrhage is a serious and sometimes fatal disaster in connexion with acute ulceration.

Perforation is very infrequent in acute ulceration. In a period of ten years at Leeds there were 61 deaths following upon perforation of a gastric ulcer in only one of which was the ulcer acute. In 117 deaths from perforation of duodenal ulcer during the same period there were eight in which the ulcer was acute. Both haemorrhage and perforation occur far more commonly in chronic than in acute ulcer. The important point which requires emphasis is that acute ulceration is preventable if the infection which causes it can be prevented or quickly removed and experience shows that to be often possible. Yet almost as often neglected.

Chronic Ulcers

Acute ulcers are ultimately chronic ulcers usually solitary. What is it that converts an acute into a chronic ulcer? There is little doubt I think that the chronic ulcer is often if not always the late result of the acute ulceration. There are perhaps many conditions which help to prevent the usually rapid healing of an acute ulcer. The acid content of the gastric juice is doubtless an important factor especially in the production of duodenal ulcer. Approximately 72 per cent. of cases of chronic duodenal ulcer suffer from hyperchlorhydria. High acidity is infrequent in cases of gastric ulcer. In my own cases the results of Rehfuss tests are shown in the following table:

	Gastric Ulcer	Duodenal Ulcer
	Per cent.	Per cent.
Anachlorhydria	12·1	5·5
Primary subacidity	15·7	4·1
Low normal acidity	7·1	1·5
Normal	9·2	5·5
High normal	15·7	9·2
Hyperchlorhydria	9·2	74·1

The X-ray chart as Hurst has insisted an ulcer matures especially I think a duodenal ulcer discloses an hypersecretor type. In patients suffering from chronic duodenal ulceration there is usually a high record content of the gastric juice they are men of vigour or strength athletic sports and often enough prowess. I have operated upon international football players cricketers lacrosse players and great runners suffering from duodenal ulcer. Such patients are often found to have a small highly placed stomachs which contract easily and empty rapidly and the acid content of the gastric juice may be such that no ordinary chart cannot record it. Many years ago I called attention to spasm in the stomach of such degree as to produce the appearance of tumour. As soon as an ulcer involves the muscular coat spasm is produced it is often considerable and in the stomach I always look—that is it is throughout confined to the same zone. When I was a student the radiologists approach was obtained in the great

* Delivered at the Royal Society of Medicine November 11th 1931

curvature causing a physiological hour glass stomach The relationship between appendicitis and gastric ulcer depends I think in part upon infection and in part upon the frequency with which severe and repeated gastric spasm is provoked by disease in the appendix This spasm is of so high a degree as to cause temporary but extreme and recurrent devitalization Behind the zone of the spasm the stomach undergoes overdistension which is sometimes considerable and is always a source of great discomfort There may also be a vasomotor spasm the result of changes of temperature or of the patient getting wet or being chilled These two forms of spasm alike produce anæmia in the gastric or duodenal walls and so prevent healing Of the evil effects of tobacco worry anxiety grief and of excessive physical fatigue I have often spoken These are some of the factors concerned not only in the creation and maintenance of chronic ulceration but also in its destiny Of the symptoms signs radiological appearances and chemical and infective conditions present in cases of chronic ulceration it is not now the time to speak

HEALING AND RECURRENCE OF ULCERS

Modes of treatment we must however consider and a careful scrutiny of claims is especially important because of the recent and as I believe exaggerated claims that have been made for a particular form of medical control In the first place it must be emphatically asserted that healing of an area of chronic ulceration in the stomach or duodenum is not only possible but in truth not infrequent This was first most clearly demonstrated by Professor M J Stewart Healed ulcers he has shown are found post mortem almost as frequently as open ulcers Perfectly healed ulcers rarely break down

Recurrence of ulceration is due to imperfect healing which leaves a still open surface free for re infection and extension of ulceration Acute ulceration is superimposed upon quiescent chronic ulceration We know by a considerable body of evidence that such quiescent ulcers may not arouse clinical recognition In the duodenum the ratio of chronic ulcers to scars in a series of 713 ulcers found post mortem was as 17 to 18 in the stomach among 322 lesions the ratio was as 11 to 12 It is true that these figures incline to favour ulcers rather than scars because of the large proportion of cases of perforation for in the Leeds post mortem room 35 per cent of patients with chronic gastric ulcer and 58 per cent with chronic duodenal ulcer have died of perforation Hart[1] found that 8 to 13 per cent of adult bodies on the post mortem table showed ulceration or scars in the stomach or duodenum the two occurring with almost equal frequency It is beyond doubt therefore that chronic ulcers both in the stomach and in the duodenum heal either spontaneously or under treatment

HÆMORRHAGE AND PERFORATION

Medical treatment is however so often perfunctory so imperfect or so brief that to its discredit a proportion—probably a large proportion—of the cases of haemorrhage and of perforation must be attributed In Leeds fatal hæmorrhage occurred in 7 per cent of all cases of chronic gastric ulcer coming to necropsy In the duodenum the incidence was 8 3 per cent and it was found that the posterior wall was involved far more often than the anterior the proportion being 14 5 per cent as compared with 0 5 per cent Perforation caused a rather larger proportion of deaths in cases of duodenal ulcer In all cases medical treatment may not have been tried for our records are silent in some of the fatal cases no opportunity having been given for the taking of a detailed clinical history It is certain however that treatment of a kind had been given in not less than 75 per cent of cases

ULCER CANCER"

Another catastrophe that may occur in connexion with gastric ulcer is carcinoma The frequency of 'ulcer-cancer' has been very variously estimated by different authorities the material used for the purpose of examination to decide the question is incomplete Post mortem specimens the parts removed at operation and clinical histories do not often afford evidence which can be usefully compared That ulcer cancer does occur in the stomach is indisputable In a series of 358 specimens of ulcer of the stomach removed by operation seventeen examples of ulcer cancer were found in that region of the stomach which chronic ulcer rather than cancer usually affects A chronic gastric ulcer in the pyloric region runs a heavier risk of cancer transformation than does an ulcer on the lower curvature One ulcer out of twenty on the lesser curvature shows carcinomatous transformation whereas one out of four ulcers in the pyloric region shows this change If the question is regarded from another aspect a different result is obtained Of 109 specimens of carcinoma of the stomach removed by operation seventeen (15 6 per cent) showed evidence of having originated in an antecedent simple ulcer

The conclusions that may be drawn from this evidence are that chronic ulcers of the stomach and duodenum do heal and may remain healed throughout the patient's life but that catastrophes of which the proportion to the total number of cases of the disease is quite unknown do occur in such numbers as to make necessary both the strictest attention to medical treatment and early recourse to surgical treatment when this has failed

INADEQUACY OF MEDICAL TREATMENT

I am accustomed to regard myself as a physician with surgical tendencies, and in this capacity I should like to call attention once more to the extreme inadequacy of medical treatment as ordinarily adopted in these conditions The position I admit is difficult The treatment by the general practitioner or physician to be really satisfactory must be strict and must be lengthy Radiological examination in cases of my own in which at operation I have had to be content with jejunostomy shows that the healing of a gastric ulcer is a slow process lasting for an ulcer the size of a shilling not less than six months Long before this time has elapsed a patient has lost all pain has experienced a return of appetite and has consequently but quite naturally become difficult The practitioner is hardly believed when he speaks of the need for continued care and a patient is apt to prove refractory or disobedient and may not willingly agree to the removal of teeth or tonsils or to other necessary measures to combat an infection which may stand in causal relation to the ulcer The number of cases coming under my own care for surgical treatment in which a really adequate medical treatment has been prescribed and honourably observed is very small Removal of all accessible sources of infection and diet drugs and absolute rest are very rarely combined in adequate degree and for a sufficient period So far as hospital patients are concerned their proper treatment is hardly possible owing to lack of beds

During the last four years encouragement has been given to those who practise medical treatment in a paper by Professor MacLean and others In this paper a series of eleven cases was examined and reports upon them were presented after varying periods of medical treatment The average length of observation was seven months—a period far too short for trustworthy conclusions My regret on reading this paper was that medical treatment was made to appear as a simple almost perfunctory, matter governed chiefly by the administration of a powder which in Leeds we had known for forty years or more as the triple carbonate On the results of this treatment

at St. Thomas's Hospital. Dr. B. E. Tompson has made an interesting report. In sixty-three cases of duodenal ulcer one third of the patients were cured, two-thirds continued to suffer or required operation. In sixty-five cases of gastric ulcer there were three deaths, three cases required operation later, two suffered again from haematemesis, eighteen continued to show symptoms, and twenty-two were relieved of symptoms and presented no radiological sign of disease. I should like to plead for a more rigid and more prolonged treatment of all early cases of chronic duodenal or gastric ulcer, and for greater attention to the removal of sources of infection. If such treatment is enforced and faithfully observed I do not doubt that fewer cases will need to be rescued by the surgeon. During the last two or three years I have returned approximately three patients out of ten referred to me with chronic duodenal ulcer in order that medical treatment might again be tried. In two of the three it has proved unsuccessful.

Surgical Treatment

If surgical procedures are followed what are we to expect? In cases of gastric ulcer the operation of choice is gastrectomy. We are rid of the ulcer then once for all, for I have never had a recurrence of ulceration after gastrectomy for gastric ulcer. The mortality in my hands is less than 2 per cent., and in respect of late results nothing could be better. It is the rarest event for a patient who has had this operation performed to return with any complaint relative to the stomach, but the operation cannot always be safely performed. If the ulcer is large and near the cardia gastrectomy is impracticable. In such cases I perform either gastro-enterostomy with transgastric jejunostomy or jejunostomy alone. Sometimes if the ulcer is small but so near the cardia that it cannot be removed without danger I perform Balfour's operation. The need for anything but gastrectomy is however rare. I have had only thirty-one cases in over 700 examples of gastric ulcer submitted to surgical treatment.

The local surgical treatment of duodenal ulcer centres round the two short-circuiting methods—gastro-duodenostomy or gastro-enterostomy—always with destruction of the ulcer and temporary closure of the pylorus. I do not practise resection. This is an operation which is unnecessary and dangerous and is attended by a risk of subsequent ulceration not less than that in short-circuiting operations. In my last 1,000 cases of operation for duodenal ulcer I have had one death. The frequency of gastro-jejunal secondary ulceration is 1·8 per cent. When this troublesome result occurs we may detach the anastomosis and restore the original passage or perform a new gastro-enterostomy or even gastrectomy. After such a gastrectomy a new jejunal ulcer may appear. I have dealt with seven such cases.

Every abdominal operation except those of grave urgency should begin with a general exploration of the abdominal cavity. In even quiescent cases I remove the appendix if it has not previously been removed and even sometimes when it has. It is impossible to tell from external examination whether the appendix is diseased or not. The appendix is certainly one of the sources of infection standing in causal relation to diseases of the stomach, duodenum, and gall-bladder, and is responsible also for high degrees of gastric spasm. In earlier cases I have many patients from whom I removed a carcinomatous stomach who, three and seven years previously, had had appendicitis. In my judgment it is more reasonable to leave the appendix even in a patient who has had appendicitis operated for and quiescent than to do so.

All patients upon whom any surgical procedure has been adopted must regard themselves as under treatment in respect of diet and drugs for not less than a year after operation, and in cases of duodenal ulcer tobacco must be scrupulously avoided because of the high increase in gastric acidity for which it is so often responsible. To all patients who have been operated upon for duodenal ulcer the following two charts are given:

Chart I.—Instructions

1. Have your teeth attended to by a dentist regularly every six months.
2. Eat slowly and chew your food well.
3. Avoid tobacco.
4. It is well to avoid all forms of alcohol. If you desire a small quantity of light wine or whisky diluted with soda water may be taken at meal times. Avoid all effervescing drinks. Avoid coffee.
5. Avoid all fruits which are acid. The skin of fruits to all fruit (whether raw, cooked, or in jam) should be removed. Avoid currants, raisins, lemon peel, nuts, figs. Orange juice with carbonate of soda sufficient to neutralise all acid may be taken occasionally.
6. Avoid all raw vegetables whether taken alone (even watercress) or in salads. Green vegetables must be passed through a sieve and mixed with butter in the form of a purée. Potatoes, also cooked, are made into the best oatmeal. Cream of wheat may be taken with cream and sugar. Sliced onions with plenty of salad oil may be taken twice or three weekly.
7. Avoid vinegar, lemon juice, sour fruits, pepper, mustard, curry, cayenne, new bread, rough meat, meat soups, underdone meat, salted fish or meat pies, made-up dishes, high game, cheese, fat meat soups. Salt if taken at all must be taken in small quantities only.
8. Take plenty of butter and cream as a dessertspoonful of oil or cream each meal is of value.

Typical Diet for First Few Months

Breakfast.—Cream of wheat, sugar, cream. Lightly boiled or poached eggs. Steamed bacon (not fried) with fat removed. Cabinet pudding. Marmalade or honey. Thin bread and butter. Bread or toast and butter, or toasted oatmeal biscuit browned. Fresh butter always.

10·0 a.m. to 11·30 a.m.—About 5 to 10 ounces of milk or Vichy water with a small teaspoonful of simple carbonate of soda.

Lunch.—Pint of soup of either milk vegetable soup. Fish as a dessert, but no salted, smoked, or fried fish. Some chicken, minced rabbit, or vegetables through sieve, minced fresh meat, or form of well-cooked milk pudding. Junket, custard pudding, Italian cream, rice. Bread and butter.

3·30 p.m. to 4·30 p.m.—As at 10·30 a.m.

5·30 p.m. to 8 p.m.—Tea. Weak China tea, cream, thin bread and butter, or rusk, sponge cake.

7.30 p.m. to 8.30 p.m.—Dinner. Light meal.

10·30 p.m. to 11 p.m.—As at 10·30 a.m., but a full tablespoonful of simple carbonate.

Between meals.—Milk, milk and lime-water may be taken as frequently as desired.

During the night.—Water may be taken as much as desired. Water should be taken at room temperature.

One further point of great importance in much of the literature concerned with gastric and duodenal ulcer deals with methods directed to two main considerations—the removal of infection and the local treatment of the ulcer by medication, extirpation, and so forth. To the consideration—often indeed necessary—given to the patient. It is not sufficient, we believe, that in these cases we should find a definite susceptibility to this disease, a habit of body, a condition of mind, a temperament, a mode of life which will not only prepare for the crisis of disease but greatly affect both our power to heal and the tendency to recurrence. Neither medical nor surgical treatment will produce their real effect until a wider conception as to their real responsibility is more adequately realised.

TREATMENT OF DYSMENORRHOEA BY EXERCISE

BY

ALICE E SANDERSON CLOW M D B Sc B S

CHELTENHAM

In response to many inquiries evoked by a recent letter of mine in the *Journal* (August 22nd 1931) on the subject of the treatment of dysmenorrhoea I have been prompted to set down some details with regard to the method of dealing with that condition by means of exercise

I wish to make it clear that my remarks refer only to cases in which the general health is good and in which there is no evidence of appendicitis or of pathological conditions of the genital organs They include however variations in the size and shape of the body and cervix of the uterus the pelvic organs being in most cases examined per rectum Having ascertained that the patient is in good health and that the disability whether it be pain vomiting, nausea headache or malaise occurs *only* in association with the menstrual period I class it as a case of dysmenorrhoea and give advice to the patient which may be referred to under the headings of hygiene, exercise baths and drugs

Hygiene

I explain to the patient that menstruation is a natural function and should be as free from pain and internal discomfort as are the other functions of the body , that in the majority of women this is the case and that since her organs are healthy there is no reason why she should not overcome her disability during the period I insist that the normal routine of life should not be interrupted during menstruation The diet daily bath and action of the bowels should be as usual There should be no reduction in the amount of exercise taken at other times Active work is beneficial as are outdoor games such as tennis and hockey walking riding cycling and rowing No extra rest is necessary during the period it may even do harm as it is important to keep up a good circulation of the blood The sensation of fatigue felt by some on the first day of the period is in most cases quickly dispelled by a warming exercise whereas it is prolonged by rest although the recumbent position produces an initial feeling of relief

Exercise

The patient s history generally serves as an explanation of the cause of her dysmenorrhoea It is usually found that the age of its onset most commonly 16 to 19 corresponds with some change in the daily routine involving more restricted time for exercise and increased hours of work owing to study for an examination or entry to an office shop or factory With the first indication of menstrual trouble the inclination is to reduce the exercise still further and if possible to lie down during the time of malaise I therefore explain that to prevent or cure the pain the circulation of the blood must be stimulated by muscular exertion If there is not time or opportunity for sufficient exercise in the open air it should be supplemented by extra exercise done at home

I have selected a few movements as being specially effective for dysmenorrhoea and have had them printed on a single sheet which I give to the patient and tell her to do them for a quarter of an hour daily for a few days before the onset of the period and on no account to fail to do them on the first and second days of the period They should be done with enough vigour to promote a sensation of heat or a gentle sweat With few exceptions this practice prevents the onset of the disability and if the pain has already begun it is usually dispelled or at least relieved as soon as the feeling of warmth is experienced Some however especially patients over 30 have to repeat the exercises two or three times on the first day in order to keep themselves free from pain After continuing the treatment for six to twelve months many are able to leave it off altogether provided they are not engaged in sedentary occupations

*Table of Exercises**

1 *Floor Polishing*—Kneel on all fours Swing right arm with elbow stiff through a semicircle as if polishing the floor, reaching as far forward and as far back as possible Repeat swing ten times with each arm

2 (*a*) *Bending*—Stand with feet apart Stretch arms above head bend forward and touch ground with knees straight Return to first position Repeat slowly eight times (*b*) *Twisting*—Stand with feet apart Stretch arms to side on level with shoulders Twist trunk round until right arm points directly backwards Twist again until left arm points directly backwards Repeat vigorously ten times (*c*) *Swaying*—Stand with feet apart Stretch arms above head Sway body and arms to right then left Repeat slowly ten times

3 *Rowing*—Sit on floor with knees straight and feet pressed against wall Lean forward and touch wall with knuckles allowing knees to bend slightly Repeat rhythmically twenty times

4 *Right to Left and Left to Right*—Stand with feet apart Swing right arm up as far as possible Bend down bringing right arm over and touch left foot Repeat six times The same with the left arm and right foot

5 *Floor Patting*—Kneel sitting back on heels Twist body and tap floor with both hands four times on left side Kneel upright Twist body and repeat tapping on right side Repeat eight times each side

6 *Bean Picking*—Throw twenty small objects such as beans on the floor Pick up one at a time and place on a shelf above the head using hands alternately Do it as quickly as possible

I have found the printed sheets very useful They save much time in the consulting room and the patient is pleased to have definite instructions Incidentally the exercises help to regulate the action of the bowels Many patients for this purpose only or for the sense of well being they promote continue the exercises daily throughout the year

A considerable number of patients have no pain but suffer from nausea or vomiting and refrain from food during the first day of the period To them I give the same treatment and teaching as that already prescribed assuring them that the vomiting will not recur if the meals are taken as usual and the exercises are done as directed In addition however for these cases I usually prescribe a sedative to be taken on the day preceding and for the first two days of the period

Baths

Most patients are still under the impression that it is unsafe to take a bath during the period so they are told that in spite of old prejudices baths are not only harmless but beneficial The complete daily wash is a necessary hygienic measure but immersion in a warm bath at night is not only salutary but checks or helps to prevent the onset of aching and discomfort There is no harm in the continuation of the cold morning bath or cold sponge during the period For women subject to severe dysmenorrhoea, who are nervous or otherwise unfit for muscular exertion immersion of the whole body in a hot bath (100°F) for ten to fifteen minutes just as the period begins is a good prophylactic against pain and will often relieve a patient already in pain Its effect being quicker is more striking than that of exercise but it has relative disadvantages in that it must be followed by rest in bed for at least an hour and unless the patient can keep thoroughly warm afterwards, preferably by muscular effort the pain is apt to return

I have never understood the rationale of the sitz bath as a cure for dysmenorrhoea nor have I heard of any real

* Printed sheets can be obtained from H K Lewis and Co, Ltd 136 Gower Street W C 1

benefit derived from it. It strikes me as a useless and chilling performance. The universal hot water bottle, though comforting to the patient, must act merely as a counter-irritant and abdomens are sometimes scarred by its use in cases of extreme pain.

Drugs

For drugs I have little use in the treatment of dysmenorrhoea and since prescribing the remedial exercises in printed form I have been spared the reproachful look of disappointment from the patient when told that there was no prescription to take away. There are however a relatively few cases in which a nerve sedative or analgesic is useful while patients are learning to trust themselves to the new practices advised. I generally prescribe ammonol 5 to 10 grains according to the case thrice daily for three consecutive days beginning with the day preceding the period if possible. The tablets are however usually discarded before the third month. I never prescribe glandular treatment for dysmenorrhoea itself but sometimes find it indicated for other symptoms in the same patient.

It is sometimes necessary to correct the prevailing impression that aperients are contraindicated during the period and to insist that a constipated state must not be allowed. During menstruation the majority of women however experience a freer action of the bowels than usual. The exercises have a regulating effect for either condition. It cannot be too often repeated that alcohol and morphine which are still prescribed as a last resource for dysmenorrhoea by some practitioners should be absolutely condemned for use in a symptom occurring early in life and liable to recur monthly for many years especially as their action is generally ineffectual. I presume that the success of the small dose of alcohol is due to its action as a vasodilator and cardiac stimulant. The hot bath acts in the same way and more rapidly. For the analgesic effect of the larger doses less palatable drugs can be substituted. Morphine is also an example of a remedy which is worse than the disease.

Besides its other advantages I would point out that a printed table of exercises is a more economical method of prescribing than monthly doses of drugs for dysmenorrhoea and that it also serves in many cases instead of aperients and costs less.

Results of Treatment

There are still some members of the medical profession as well as the laity who see danger in the treatment of dysmenorrhoea by exercises and baths. In answer to these I can state that in my work among schoolgirls and training college students I have personally noted the effect of the practice of continuing games and other activities throughout the period on 2,300 girls. Six only of these have reported that games at the period did not suit them but in not one case out of the whole number have I heard of any ill effect noted either at the time or subsequently.

In nearly twenty years of practice I have had just over 400 cases of dysmenorrhoea of varying degrees of severity which have been cured or relieved by treatment with baths and exercise. Fourteen patients have complained that they felt worse after the exercises though no increase of disability persisted. But since three of the severest of these cases have through force of circumstances ultimately given themselves up to vascular exertion I have ceased to be discouraged by the failures. Very successful results of the treatment of dysmenorrhoea by special exercises in cases free from pelvic organic findings among college women in America are quoted in an interesting article by Drs. Margaret Bell and Elsie Parsons.[1]

To those who see risk in the remedial exercises I would ask what alternative treatment they would recommend. Rest and drugs must be regarded as merely palliative. Dilatation of the cervix is the only time-honoured medical cure. It sometimes has to be repeated and the risks involved are surely much greater. Of diathermy I have little experience but I recommend it to patients unwilling to adopt the usual treatment.

It is of course important to exclude appendix trouble before advising strenuous exercise but caution in this respect is just as necessary during the inter-menstrual period and applies equally to both sexes. I have not yet found a case of appendicitis in which abdominal pains occurred *only* during the period but owing to the greater impression made by the dysmenorrhoeic pain careful inquiry is sometimes necessary to elicit accurate information with regard to abdominal pain at other times.

For severe dysmenorrhoea the set exercises are generally necessary as a substitute for or in addition to any outdoor games or sports. They can be more easily regulated in time and amount to suit the needs of the patient.

Women in Industry

It is the freedom from risk in such treatment which has prompted Lady Barrett and myself in response to requests from social workers to publish a leaflet entitled *Advice to Young Women Concerning the Monthly Period* in which the hygienic measures described above are stated as simply and briefly as possible and the table of exercises is appended.

The advice given is on the same lines as that contained in the leaflet for schoolgirls issued by the council of the Medical Officers of Schools Association.

The main purpose of the leaflet is for distribution among healthy girls and women engaged in industrial occupations with the object of reducing the incidence of disability during the period. It seems that dysmenorrhoea severe enough totally to incapacitate workers is not common but a considerable proportion of women especially those with sedentary and standing occupations suffer minor pains and discomfort every month. With this unnecessary suffering there must inevitably be an unnecessary though unrecorded diminution in the output of work.

This leaflet can also be obtained from Messrs. Lewis and Co. I am finding it helpful too for private patients as it ensures a fuller understanding of the instructions given in the consulting room.

BONE GRAFT AND FUSION OPERATIONS FOR THE SPINE*

BY

S. A. S. MALKIN, M.B., F.R.C.S.Ed.

SURGEON TO CROYDON GENERAL HOSPITAL AND TO THE CROYDON ORTHOPAEDIC HOSPITAL

(From the Spinal Unit)

Operations for spinal fixation in adult cases of tuberculosis are in the absence of certain contraindications widely advised as a useful adjunct to treatment. That there is no such unanimity as to the precise method of attaining fixation is shown by the fact that from time to time new methods or modifications of older methods are invented and described. It is because the relative merits of such methods have received little attention in our literature that this paper has been written. Its object is to consider some of these methods and to arrive at some conclusions as to which of them from simplicity and wide applicability is the best. It is recognized that all these operations have their origin in the methods

* From a paper read at a meeting of the British Orthopaedic Association at Newcastle-upon-Tyne, October 30th, 1931.

of Hibbs and of Albee I shall first describe briefly the essential points of these methods Both aim at fusing the posterior parts of the affected vertebrae together with two or three vertebrae above and below them In Albee's method this is done by splitting the spinous processes and placing in the groove so formed a graft taken from the shaft of the tibia, if the deformity is severe, flexion of the graft is obtained either by shaping it or by making saw cuts parallel to its long axis so that it can be bent Hibbs's method comprises fusing the laminae of the corresponding area into one solid mass To do this the ligamentum subflavum and all soft tissue attached to the laminae must be dissected away and the intervertebral articulations destroyed, bony bridges are then made by turning down small bone flaps from the laminae and finally the spinous processes, previously broken down are placed so as to assist in forming the bridge I had the opportunity some years ago of seeing both these operations performed by the originators in their own hospitals Under these conditions both look easy to perform and there is no doubt of their effectiveness when however one attempts to perform them oneself both present certain difficulties

Gibson of Winnipeg in a recent article mentioned some of the difficulties in the Albee operation The degree of development of the spinous processes varies considerably in different individuals—sometimes extreme flexibility makes it hard to split them and difficulty arises in gauging the depth of the groove which may easily be either too deep or too shallow Again when a lateral curve is associated with the usual kyphosis the spinous processes are not in line, and this may call for the very difficult task of cutting a graft curved in two planes Further there is a risk that the use of a mallet and chisel so near the infected area may cause the infection to light up Another danger is that the graft being relatively small may later be fractured particularly as a result of torsion of the body Hibbs's operation has this advantage over Albee's that the fusion is more general and the method can be used in all degrees of deformity in addition the removal of the prominent spinous processes improves the appearance and diminishes the risk of pressure both during the early post operative stages and later when a spinal support is applied It has however some disadvantages chief amongst which are the meticulous care required the time necessary to perform it and the consequent increased risk of post operative shock The operation is more difficult to perform in the lumbar than in the thoracic region In the latter region the laminae overlap to a greater degree there is consequently a smaller gap to be bridged and also they are more superficially placed For these reasons it is agreed that there are difficulties in both the operations and it is as a consequence of this that various modifications have been made I propose to mention three of these

1 Hey Groves has used a method in which two grafts are placed one on each side of the spinous processes and sutured or bolted together By this means a double thickness of graft is obtained and the strength of the spinous processes is not impaired

2 Gibson[1] of Winnipeg uses a method in which a solid graft with two clothes peg ends is cut from the tibia the spinous processes of the affected vertebrae are detached and the sides of the spinous processes of the two vertebrae above and below are cleared and made raw The graft is then applied over the raw surface of the bases of the detached processes while the two limbs of the clothes peg ends lie one on each side of the spinous processes above and below

3 In a third method grafts from the tibia are placed in the vertebral grooves of the laminae This operation consists in stripping with a large chisel the periosteum and muscles from the sides of the spinous processes and from the laminae, and freshening the surfaces so exposed When this has been done grafts from the tibia shaped or straight as need be, are placed in the grooves The grafts are then held in position by suturing the muscles over them after removing the prominent spinous processes This method has been strongly advocated by Wheeler, who however puts the graft on one side only He has shown that a graft so placed both survives and functions

While the methods of Hey Groves and Gibson have both been proved effective and advantageous they possess certain disadvantages It is obvious, on theoretical grounds, that when acute kyphosis is associated with lateral displacement they must be very difficult to perform In addition they both presuppose in the operator a manual dexterity which may not be present

The method of placing one graft in each vertebral groove is mechanically sound, combining as it does the advantages of the Hibbs and Albee operations It is easy

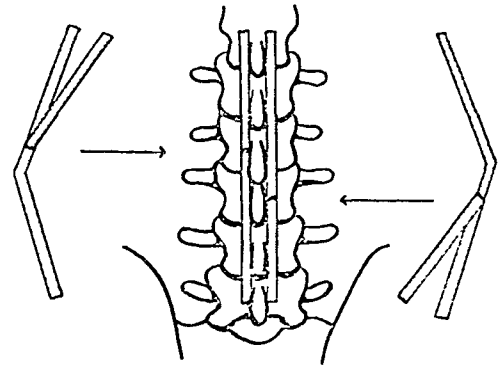

Diagram showing angular grafts cut from the tibia and broken to fit in acute kyphosis

to perform therefore causing less post operative shock it is adaptable to all types of deformity in the dorsal and lumbar regions In effect the graft is really a series of small grafts uniting adjacent laminae It thus follows that in a very angular kyphosis the graft can be broken without materially weakening it provided the fracture is made over the centre of a lamina and not at a corresponding point on each side In the case of a lateral deformity it may be that one graft only can be used—on the concave side of the spine It will readily be seen that although only tuberculosis has been referred to the method can be used equally for certain fractures of the spine and other conditions needing spinal fixation

Having considered the method of fixation reference should be made to one other point—the extent of the operation It has usually been taken for granted that the fixation should include two or three vertebrae above and two or three below those affected Indeed one great criticism of the operative treatment of tuberculosis is the resultant immobilization of a larger area of the spine than is actually affected by disease In the thoracic region this is not of so much importance as in the lumbar region where any unnecessary loss of mobility is a disadvantage This is especially the case where x rays show that the disease is limited to two or three vertebrae only The great risk to a patient successfully treated by conservative methods alone is that a sudden jar may strain a fibrous ankylosis and cause a recurrence of symptoms The effect of a spinal graft is to take the weight off the vertebral bodies and transfer it to the articular processes Theoretically therefore recurrence should be prevented by short grafts joining together the laminae of the affected vertebrae where the disease is very limited or where it is more extensive including one above and one below

During the last few years I have had to consider very carefully what is the best method of fusing the spine. After a trial of other methods I came to the conclusion that from a practical point of view the method of the double graft in the vertebral grooves was the soundest, the simplest, and the most generally applicable. During the last twelve months I have used it in eight cases of various type. While it is yet too early to speak of the final results in all cases I have found the method (sometimes slightly varied) uniformly satisfactory.

LICHEN URTICATUS: A DIFFERENTIAL DIAGNOSIS OF SMALL-POX

BY

HERBERT D. CHALKE, M.A., M.R.C.S., D.P.H.

[illegible]

During an epidemic of small-pox, especially in its modified form, errors in diagnosis are common, and the rashes of other diseases are often mistaken for the variolous eruption. In the majority of cases of wrong diagnosis the patient is found to be suffering from chicken-pox, but measles, scarlet fever, specific eruptions, and drug rashes are also responsible for mistakes. Acne and impetigo may also cause confusion, while cases of pediculosis or mosquito bites have found their way to the small-pox receiving station on many occasions. In children, though not so often mentioned in the textbooks under the diagnosis of small-pox, lichen urticatus is responsible for many [illegible]. Fibulis referred to the possibility of its being mistaken for small-pox, but he was of opinion that differentiation between the two diseases should present little difficulty. A number of cases of lichen urticatus were examined during 1930 and 1931 in the Metropolitan Borough of Poplar. Many of them were brought under observation as a result of their being notified as cases of small-pox; others were visited at the request of the medical attendant, who considered the rash suspicious or the graver cases. On a few occasions the rash was mistaken for chicken-pox or measles. In all about forty cases were examined during fourteen months, sixteen being notified as small-pox or possible small-pox, and two as chicken-pox.

Lichen Urticatus

Lichen urticatus, or papular urticaria, is one of the commoner skin diseases of early life. It differs from other forms of urticaria because the characteristic lesion is a papule, rather than a wheal. The disease commences as an eruption of papules of measles, a quarter to one-half an inch in diameter, each arising a small papule at its centre. The papules rapidly [illegible] for minutes to an hour or so, and the [illegible] during [illegible] eruption, in many cases, persists. Fresh crops of lesions may appear at any time during the course of the disease. The papules soon assume the colour of the surrounding skin, and a complete disappearance of the [illegible] takes place in the same manner that it occurs in measles. Many of the papules are surmounted by minute vesicles, as in common forms of small-pox. Scratching is considered a common and disturbing result in the appearance of blood crusts. When the earlier stages are passed, the rash is distinguished from a papular [illegible] by the [illegible] stage. It is because the [illegible] stage is so short-lived that it is very often missed by the medical attendant. Indeed, it sometimes escapes the notice of the mother, who can only usually describe the rash as [illegible] mosquito bites or [illegible] bumps. Children up to 2 years of age are most susceptible, and in numerous instances a history of previous attacks may be obtained. Primary lesions, as a rule, [illegible] infancy, but cases have been described in which the first attack took place as late as the fourth year of life. Many authorities have noted that the lesions of prurigo show a preference for the limbs, especially the extensor surfaces, while [illegible] and flexor surfaces tend to escape. Hartzell is of opinion that the [illegible] of [illegible] [illegible] and strip [illegible] are [illegible] severe forms of [illegible]. Variations in the [illegible] of lichen urticatus. Macleod states that in age the [illegible] upper extremities than the [illegible] on the [illegible] parts, especially the lower part of the [illegible]. Wilson and Morris consider that the rash of lichen urticatus [illegible] a predilection for the trunk as opposed to that of prurigo, in which the lesions are spread on the [illegible] and on the flexor aspects of the limbs and [illegible] on the extensor aspects. According to Radcliffe-Crocker the distribution of lichen urticatus is [illegible] that of the eruption of small-pox.

Papula urticata—the occurrence of wheals as a result of scratching on the eczematous [illegible]—is considered in connexion with the rash of lichen urticatus, but by no means a constant phenomenon. In the cases examined [illegible] could not be noted, but this may be explained on the fact that often the eruption was of many days' duration when first seen. Nevertheless, only a few of the children are said to be the least [illegible] from this complaint, while prurigo is a common accompaniment of [illegible] and pruritus.

Records of Cases Examined

In thirty-eight children the ages at admission were as follows:

1 year	1	3 years	11	5 years	3	7 years	1
2 years	3	4 years	11	6 years	3	8 years	1
3 years	4	4 years	7	6 years	3	9 years	1
3 years	5	4 years	8	6 years	3	10 years	1
3 years	6	4 years	8	6 years	3	11 years	1
3 years	7	4 years	8	6 years	3		
3 years	8	4 years	8	6 years	3		
3 years	9	4 years	8	6 years	3		
3 years	10	4 years	8	6 years	3		
3 years	11	4 years	8	6 years	3		

The majority were visited during the months of April, May, June, and July, a few during September and the winter months. In 40 per cent. of the cases the rash was entirely popular at first examination and on subsequent visits. The remaining children showed an urticarial element in addition to the papular. The papules were usually small—pin-head size—but were sometimes much larger, reaching a diameter of a quarter of an inch. In a few cases the rash was represented by [illegible] and a few lesions, but these were exceptional. Some cases of extreme severity were encountered, where [illegible] the papules were almost [illegible]. In a few [illegible] the rash [illegible] a [illegible] [illegible] to small-pox. In 70 per cent. of the cases there was an excess of the lesions [illegible] the [illegible] [illegible] to them. In the great majority of cases the papules were [illegible] on the forearm and [illegible] and [illegible] and [illegible] and [illegible] on the extensor surfaces than on the flexor. When the [illegible] [illegible] was present, it usually [illegible] on the [illegible]. The face was affected in only a few children, and then to a [illegible] small extent, while [illegible] were [illegible] in the axillæ and [illegible]. In its preference for [illegible] and [illegible] of [illegible] at the expense of [illegible] [illegible] the eruption still [illegible] that of small-pox, but its [illegible] on the face was not in keeping with the distribution of [illegible]. Three of the children showed the [illegible] eruption on

the soles and in four cases it was also present on the palms, the papules being hard, firm and 'shotty' to the touch The rash was fairly symmetrically arranged on both sides of the body The disease persisted for periods varying from a week to two months the seat of the eruption being marked by slight pigmentation Rarely unless secondary infection occurred was there scarring Three patients had the lesions secondarily infected one of them a female of 18 months showing a severe moist, eczematous condition on the limbs and buttocks ten weeks after the commencement of illness This proved very resistant to treatment Another child 2 years of age was first examined after secondary changes had taken place The rash was composed of scabs an eighth to a quarter of an inch in diameter, and where these had been

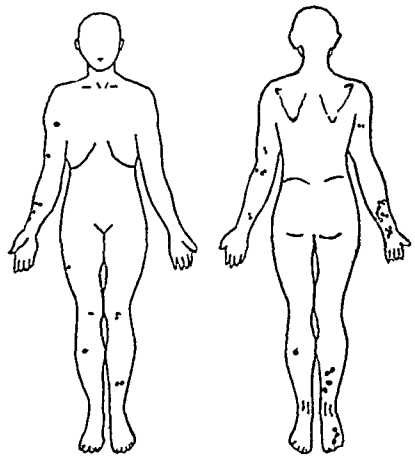

Fig 4.—Chart showing distribution of rash in a typical case

knocked off a moist oozing surface was exposed There were papules on the soles and a few fresh papules and macules in various situations This child was well nourished and appeared otherwise healthy In a number of cases it was possible to obtain a history of previous attacks tending to occur in warm weather The mother sometimes called the complaint hives teething rash or sugar rash Home conditions were usually far from satisfactory but the children themselves were on the whole clean and well nourished There did not appear to be any connexion between breast or artificial feeding and the incidence of the rash

Differential Diagnosis

There should seldom be any great difficulty in differentiating between small pox and lichen urticatus Mistakes are most liable to occur when the urticarial stage has passed and the rash is entirely papular simulating the papular stage of variola During an epidemic of modified small pox an eruption which predominates on the limbs —more especially on their extensor surfaces—may readily be misdiagnosed unless the individual lesions are carefully examined In every case in which the least doubt exists the eruption should be mapped out on a chart This in itself is generally sufficient to enable a correct diagnosis to be arrived at If the rash is moderately profuse on the limbs and absent or sparse on the face the evidence is against the disease being small pox Again whereas in lichen urticatus papules may be present on the upper and lower extremities at the same time the lesions of small pox are always at a later stage of development on the face and arms than on the legs One would therefore expect to find vesicles on the face when the rash on the legs was papular

As distinct from the papule of lichen which appears to be *on* rather than *in* the skin the lesion of small pox commences in the deeper layers These differences may readily be appreciated on palpation Although a modified small pox rash shows many superficial papules, *some* of them will always be deep whereas in lichen urticatus all are superficial The small pox lesion is inflammatory and passes through the stages of vesicle and pustule before desiccation takes place The lichenous papule is usually the colour of the surrounding skin and though often capped by a small vesicle or crust it remains papular unless there is much scratching and consequent sepsis This stage is not likely to be confused with small pox The discovery of one or two urticaria like lesions is a very valuable aid to the diagnosis of lichen urticatus These can hardly be confused with the areolae which so often surround the small pox papules, vesicles or pustules Severe pruritus, which does not occur in small pox may lead to an erroneous diagnosis of scabies but the absence of the characteristic burrows is sufficient to eliminate this ailment The varicelloid rash is heterogeneous and its papular stage very short-lived Vaccinal lichen two cases of which were reported on by the author [6] is almost indistinguishable from lichen urticatus It appears at about the eleventh day of successful vaccination and is not of common occurrence Unlike the infectious diseases lichen urticatus is not preceded by a period of pre eruptive illness but this is sometimes true of modified small-pox

Conclusions

Lichen urticatus frequently bears a striking resemblance to small pox in the distribution of its lesions The papules very often prefer the limbs to the trunk, and the extensor surfaces to the flexor The face receives little rash in the majority of cases

The lesions themselves differ markedly from those of small pox and this disease may be eliminated by careful examination

The illustrations reproduced on the Special Plate show an eruption of lichen urticatus before and after secondary changes had taken place

My acknowledgements and thanks are due to Dr W Allin Young D S O medical officer of health for the Metropolitan Borough of Poplar for permission to publish these notes and for valuable help in the collection of data

THALLIUM ACETATE IN THE TREATMENT OF RINGWORM OF THE SCALP *

BY

JOHN T INGRAM M D M R C P

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT THE GENERAL INFIRMARY LEEDS LECTURER ON DISEASES OF THE SKIN UNIVERSITY OF LEEDS

(*With Special Plate*)

The adventures of thallium acetate in the practice of medicine and particularly in relation to the treatment of ringworm of the scalp have never been too happy After its rejection by Sabouraud in the early part of the century little was heard of this drug until Buschke published his work in 1914 Subsequent reports from this author in 1926 together with the experiences of Cicero in Mexico published in 1918 and 1922 appeared to have established the use of the drug upon a sound basis but as further literature has been forthcoming doubts

* Read to the Section of Dermatology at the Annual Meeting of the British Medical Association Eastbourne 1931

have caused a human life. The point at present [illegible] must [illegible] and control of the [illegible]. Dr. [illegible] the disease and the [illegible] in [illegible] and [illegible] cases like Wright gave reasons why he preferred thallium acetate as [illegible] [illegible] to [illegible]. In December 1926 Lynch and Sewell [illegible] that thallium acetate should not be used as an ointment [illegible] in the treatment of ringworm of the scalp and as an alternative to the B. [illegible] they [illegible] that the [illegible] e. Eczema was almost intolerable to the in the treatment of ringworm in such [illegible] Gerundo and Pecora and later Pecora[illegible] used thallium acetate to a [illegible] [illegible] that [illegible] ways in the treatment of ringworm and [illegible] the views opposing the use of this drug.

At the same time [illegible] cases treated by the [illegible] salving of [illegible] and [illegible] have repeatedly come [illegible].

We [illegible] [illegible] sufficient about the [illegible] of cases of thallium acetate to inquire into the [illegible] [illegible] of the matter but such communications as I have put before you have call for some attention [illegible] of the literature as well as personal communications [illegible] to the belief that [illegible] with the greatest caution in the use of this drug in the treatment of ringworm of the scalp and to determine the limits of safety and the rule governing the use of the drug. It seems to me that it can be of no use unless the procedure is simple and can be pursued with [illegible] safety.

That the routine treatment of ringworm of the scalp demands some [illegible] [illegible] [illegible] will be generally accepted. There are only two such measures known to us [illegible] and thallium acetate. I think we can [illegible] admit that a more [illegible] [illegible] [illegible]

British Pharmacopoeia and are in daily use one merely needs to adhere to the correct dosage and method of administration

Routine Procedure

My own practice gradually formulated with increased experience is to have the child's urine examined If this is clear and clinical examination is satisfactory the child is weighed naked To render the procedure as simple as possible the weight in pounds is multiplied by four which gives the required dose of thallium acetate in milligrams This method appears to me simpler and safer than the usual practice of weighing in kilograms and varying the dose per kilogram as between eight and nine milligrams of thallium acetate The following points should also be observed

1 If the dose is *under* 200 mg treatment proceeds as in the case of ordinary out patients

2 If the dose is *between* 200 and 250 mg the over cautious may treat the case in bed but it is satisfactory to proceed as with cases of Group 1 as long as the child is kept under observation

3 *Between* 250 and 300 mg great caution is exercised and the case is treated in bed

4 More than 300 mg is never administered

The average age of a child requiring 200 mg is 7 years 250 mg 9 years 300 mg 12 years It will be seen that there is little danger in treating children up to the age of 9 years

It is therefore very difficult when these precautions are taken for a child to receive anything considerable in the way of an overdose even if slight errors are made in the calculations or the scales are inaccurate Any case demanding more than 200 mg goes under special observation

It is unwise to use solutions of the drug since this may lead to errors in dispensing Now that tablets of varying strength are dispensed in different colours there is little excuse for errors in dispensing this dangerous drug In my own cases the tablets are swallowed by the child who is subsequently given a drink of water There is less chance of the child not receiving the full dose if this practice is followed There is however, considerable room for further improvement in the wholesale dispensing I do not consider it wise to repeat the treatment should the measure be unsuccessful but in any case an interval of not less than three months should elapse

Local Treatment

The other matter to be considered in thallium treatment concerns the local measures employed An elaborate treatment involving skilled attention—the use of epilation forceps adhesive strapping collodion, etc —is not in my opinion likely to bring the measure into the realm of practical politics The parents the patient and the practitioner will soon find no time for such things It is necessary to get all the stumps removed as quickly as possible to prevent reinfection of the new hair which is already beginning to show at the end of three weeks If the whole scalp is painted *three times a day* with 2 per cent tincture of iodine *every day from the onset of treatment* this provides adequate anti parasitic action while at the same time a coarse desquamation of the scalp is effected reaching its height towards the end of the third week The scalp should not be washed during the first two weeks but should be washed once or twice during the third week The desquamation of the scalp brings away the infected hairs with it and the whole procedure is effected with a minimum of trouble to patient and doctor It is highly efficacious and simple I would emphasize that the *whole* scalp should be painted daily and that no other application should be used—particularly no ointment It is my practice to have these cases attending once a week for the first three weeks to see that the procedure is being carried out accurately After this they attend once a fortnight for a further six or eight weeks The treatment is stopped at the end of that time

Results

I believe these suggestions for routine treatment are perfectly safe and simple They have reduced the burden of the ringworm cases in my clinic to a negligible factor They have also reduced considerably the period during which observation is necessary In the past three years I have treated fifty one cases of ringworm of the scalp by *x* ray therapy with completely successful results I have treated one hundred and one cases with thallium acetate—ninety-four cases successfully and seven unsuccessfully In the earlier period I had three cases of severe toxaemia, but since then I have not seen anything that could be regarded as sufficiently severe to warrant the patient being kept in bed

Summary

1 There is no serious evidence against the use of thallium acetate in the treatment of small spore ringworm of the scalp if the drug is properly administered

2 Though toxic symptoms may occasionally be encountered they are seldom severe and the patient invariably recovers completely

3 There is no evidence whatever to suggest that thallium acetate affects the growth or development of the child or effects any permanent damage to any organ

4 A simple method of procedure has been described which, it is suggested is perfectly safe and brings the practice within the scope of the general practitioner

LOW VISCERAL TONE

BY

D W CARMALT JONES D M F R C P.

DUNEDIN N Z

(With Special Plate)

Some years ago I was consulted by a lady of whose domestic circumstances I happened to be aware She was 47 years of age and had been a vigorous athletic woman she complained that everything was a trouble and that she was depressed miserable and lachrymose I found her development and nutrition fair but she was in a condition of general slackness her heart gave extra systoles her blood pressure was 90/60 her tongue was flabby and indented by the teeth and her right kidney was readily palpable I easily elicited the information that her life had been one of continuous anxiety on account of her family affairs

The physical slackness mental depression extrasystoles, low blood pressure thin tongue and visceroptosis appeared to make an easily comprehensible syndrome and I have found it in a good many cases since though not all of the items are always present The history and symptoms are generally very similar the extra systoles often occur at night and disturb sleep and sinus arrhythmia is often manifest The low blood pressure is not invariable I have tabulated the chief findings in

Case	Age	Symptoms	Nutrition	Tongue	B P	Digestive System	Heart	Nervous System	Duodenal Ulcer
1	47	Dyspnœa, faintness, pain in chest	Fair	Thin, flabby, no definite papillæ	90/60	—	Extrasystoles	—	—
2	43	General pain in chest, dyspnœa	Poor	Thin, flabby, no definite papillæ	85/55	—	Small pulse	—	—
3	36	Sore throat	Very thin	Large, flabby, indented	85	—	Slow arrhythmia	—	—
4	42	Pains in chest, dyspnœa, faintness, sore throat	Very thin, flabby, pale	Large, flabby	100/70	No abnormality found	Slow arrhythmia	—	—
5	—	Pain in chest	Thin	Flabby, indented	85/55	No abnormality found	—	—	Small ulcer
6	—	Dyspnœa, pain in chest, sore throat	Very thin, pale, flabby	Flabby	100/70	No abnormality found	Slow arrhythmia	—	Small ulcer
7	32	Dyspnœa	Thin	Thin, indented	85/60	No abnormality found	—	—	—

this and six other cases in the table. All the cases are in women and five out of the seven are married or are widows; two are aged between 20 and 30, two between 30 and 40, and three between 40 and 50. The symptoms have thus generally become obtrusive in early middle life.

Case 7 was under my care in Dundee Hospital and has been more fully investigated. Her symptoms were mainly dyspnœic, but the appearance of her tongue immediately directed attention to this syndrome. No gross lesions were detected. The results from the laboratories and x-ray department were as follows:

Barium meal and x-ray: gross ptosis of the stomach, practically 30 per cent delay in emptying, no organic lesion detected. Gastric analysis: HCl was absent from the stomach contents for the first hour and rose only to 20 during the experiment. 20 c.cm. of N/10 soda required to neutralise 100 c.cm. of gastric juice. Blood chemistry: total non-protein nitrogen 28 mg. per 100 c.cm., sugar 0.09 per cent. Basal metabolic rate +9 per cent.

Thus all functions appear to be carried out to a minimum standard, with the exception of the blood pressure, which is slightly higher than normal. Otherwise metabolism, secretion and peristalsis are all sluggish, though not to a positive pathological degree. No history of anxiety was obtained, but the facies of the patient was highly expressive of it. The most probable explanation of this case, and perhaps of them all, is functional insufficiency (Fernanand) of the suprarenal capsules from exhaustion. Emotion, as Cannon long ago demonstrated, stimulates the suprarenals with secretion of adrenaline into the blood, and when anxiety is long continued in any case the vigour of these glands is likely to be exhausted. This would account for the low—though not pathologically low—blood sugar. It would also account for the low blood pressure commonly found. Probably the suprarenal cortex is not affected alone, and the low basal metabolism suggests a similar trend. The low non-protein nitrogen in the blood is not so easily explained, but may be due to a sluggish action of the liver. All of these functions are only a little below normal, but together they produce a new depressing syndrome. In treatment of the last case the abdomen was supported on a double spica bandage on account of the visceroptosis; glucose drinks were given to increase the sugar intake, and also to stimulate the liver together with eggs to increase the blood nitrogen, and a tonic mixture to increase the metabolic rate. In cases where the blood pressure was low I have found spirochæta but that drug is not always well tolerated and sometimes causes nausea. The general condition improved considerably, and the patient gained 5 lb. in three weeks—5 st. 7 lb. to 5 st. 12 lb. The examinations were not repeated.

Similar cases could be cited as occurring in cases of chronic ulcer which have led to the diagnosis of the symptom-complex with spasm of the pylorus and consequent dilatation of the stomach, when that has not been present. The condition appears to me to be a great deal more frequent than spasm of the pylorus, and to be a true visceroptosis, affecting the whole alimentary tract and also the circulatory system. The tone is quite abnormally relaxed. The state of the tongue is most characteristic, and once that is observed one can feel sure of finding other morbid signs in the syndrome. It is usual to look at the tongue as a specimen of the mucous membrane of the alimentary tract; it is at least as important as a specimen of the muscle of the tract. The tongue in this condition is obviously of low tone; it is thin, almost like a dog's tongue; there is a little hump along the dorsum on each side of which there is a longitudinal groove, and the edges are curled up and indented by the teeth. It suggests a thin slice of cooked ham. Photographs rarely indicate it well, but something may be made of the figure reproduced in the Plate from a case in which the tongue is very typical in the flesh. In any case with such a tongue I should expect to find a floating kidney and visceroptosis is almost certain to be present. The low blood pressure, the sinus arrhythmia and extrasystoles often disturbing sleep seem to me to be explained in the same way.

No explanation is assumed for these observations. Professor Fernanand claims to have been the first to describe chronic intermittent hypotension in 1913, which he forecalls constitutional angeioparesis. He observed it to be due to functional insufficiency of the adrenal capsules. He describes [illegible] general weakness, vertigo and visceroptosis, but in his summary makes no mention of the tongue.

Summary

A series of cases is described in which parietal and emotional weakness are found with low blood pressure, visceroptosis, and a characteristic state of the tongue; a case more closely investigated showed low metabolism in a mild degree. The patients are women who have been subject to long-continued anxiety, and the condition is ascribed to functional insufficiency of the suprarenal capsules.

TUBERCULOUS CERVICAL ABSCESS

HAMILTON BAILEY, F.R.C.S.

[illegible]

The term cervical abscess [illegible] of the gross pathology of this condition see Fig. 2. Commonly it is most often associated with a [illegible] upper [illegible] chain of [illegible] glands. Fig. 1 or Plate [illegible] the [illegible] gland and the [illegible]. In this site it is necessary in the first instance to exclude the possibility of the swelling being a branchial cyst. Elsewhere I have drawn attention to the [illegible] to which the latter condition is [illegible] the former and indicated how a differential diagnosis can often be made. In this communication it is proposed to discuss the treatment of [illegible]

cervical abscess To my mind, the development of such an abscess while the patient is under observation is a cause for regret for had the breaking down gland been excised before the fascial erosion the pathological process could have been terminated abruptly Be that as it may *no one will question that if the superficial abscess is* allowed to break through the skin and a sinus appears this at any rate is an occasion upon which the observer might well say with Whittier What might have been!

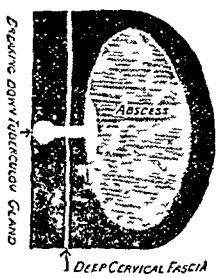

Fig 3

Aspiration of the Superficial Abscess

Repeated aspiration sometimes cures the condition It must be carried out every time the abscess cavity commences to fill a event which recurs until the ts of the gland or glands below extruded During this variable patient to be placed in the best ght is the most important of der constant observation (prefer tion through healthy skin at one the oblique method of Calot has It must be admitted however that slow and rather uncertain As I have seen is far from successful In one patient the needle has been introduced directly and the puncture hole is leaking In another the abscess has refilled more quickly than anticipated and the unobservant sufferer has failed to report the matter before the appointed day In a third the patient thinks he has knocked his neck At all events, the very thing which it has been the clinician's

street to avoid is present—namely a patch of skin over excentre of the swelling sodden reddened and threaten m to break down (*Fig 2 on Plate*) It was in cases such w these that I first employed collar stud excision—ch merely scraping out but completely excising the pra ased group of glands beneath the deep fascia

roo

I (

Excision of the 'Collar stud'

An oblique transverse incision is made over the swelling should there be a small area of unhealthy skin near the proposed line of incision this is excised elliptically To the skin edges moist gauze pads are accurately attached The anterior border of the sterno mastoid is now defined Special attention is directed to the character of this muscle for the following reason if it is flattened out over the swelling it is highly probable—in my experience certain—that one is dealing not with a tuberculous abscess but with an inflamed branchial cyst Even after the special trouble which I take to exclude the latter condition it was on three occasions only the sign of muscle flattening at this stage which indicated the true nature of the swelling These diagnostic humiliations were due to therapeutic aspiration which robs the branchial fluid of its characteristic cholesterol In one case tubercle bacilli as well were demonstrated in the fluid In collar stud abscess the exposed sterno mastoid feels stiffened and somewhat thicker than normal With a little dissection in front of this structure the abscess is opened and pale yellow pus exudes The cavity is emptied and mopped dry, and as one peers within a lining of soft dark red granulations called Volkmann's membrane is seen Here and there some inspissated material clings to the walls and cannot be wiped away These patches are dissected off and in the same way the sterno mastoid is cleaned until the whole cavity presents an even reddish hue A Watson Cheyne seeker is employed to find the tiny opening in the deep fascia as shown in the drawing reproduced below The opening is enlarged by stretching and the finger explores beneath By this method the diseased glands, which up to this time are not at all apparent can soon be found One now settles down to a careful dissection ligaturing

Fig 4.—After the abscess cavity has been emptied the hole in the deep fascia leading to the breaking down gland or glands is found by a Watson Cheyne seeker

bleeding points as they arise When dissection is completed it is quite easy to determine with the exploring finger if any enlarged gland in the neighbourhood has been overlooked Having dried the cavity, and been satisfied that no bleeding point has been missed gauze soaked in iodine is packed into the wound and left *in situ* for about two minutes A minute drainage tube is passed through a stab wound made with a tenotome through the back of the neck The object of the drain is to prevent a haematoma It is usually removed in twenty-four hours The platysma and superficial fascia are united by a running suture of the finest catgut and the skin is approximated with Van Heiff's *series fines* On the fourth day every other clip is removed and artificial sunlight treatment commenced

Collar stud Abscess in the Submaxillary Region

After the upper jugular chain the glands in the submaxillary region are most frequently attacked The following points concern excision of the 'collar stud' in this situation The incision is made three quarters of an inch below and parallel to the inferior border of the jaw An endeavour is made to avoid damaging the mandibular branch of the facial nerve—a branch more often severed by accident than is any nerve in the neck As in this part of its course the nerve lies just beneath the platysma we dissect and retract the lower cut edge of the skin in order that the platysma may be incised at a lower level The muscular sheet is then retracted upwards and with it the nerve Fortunately even if the nerve is damaged the resultant dropping of the corner of the mouth generally passes off in a few weeks As the skin incision lies in the shadow of the jaw the cosmetic results of the operation are particularly gratifying

Supraclavicular Triangle

In most of the cases which I have seen the skin has already become red and sodden over a large portion of the swelling If the posterior border of the fossa be chosen for the incision the necessary undermining imperils the vitality of the integument still further As the scar is of less importance here an oval shaped incision in the fossa itself is employed There is a convenient pad of

fat overlying Sibson's fascia and this provides an excellent plane in which the dissection can proceed once the opening in the deep cervical fascia has been enlarged.

These observations are founded upon twenty-six examples of collar-stud abscess treated by excision. Unfortunately attention occurred in all save two born of these being in the supraclavicular region and having advanced sinus involvement all the end-results have been satisfactory. I desire to make clear that in each case the glandular involvement was strictly limited. Indeed it has been my experience that the tuberculous process is usually circumscribed in this condition. In all cases artificial sunlight treatment was commenced soon after operation and where there were dental caries and diseased tonsils these received appropriate attention.

Finally it is submitted that for those who must be educated and reindered fit for the battle of life with as little delay as possible a complete excision of a collar-stud abscess is a form of treatment which cannot be bettered.

CEREBRAL ANEURYSM WITH RECURRENT LEAKAGE

BY

R. M. J. HARPER, M.A., M.D. Oxon.

ASSISTANT MEDICAL OFFICER, [illegible] DISPENSARY

(*With Special Plate*)

The patient, a single woman of 41, had enjoyed such exceptional health that except for an appendicectomy during the war she had never had to consult a doctor. Since October, 1929, she had complained of headaches before her menstrual periods, for which she took large doses of aspirin, although it is said by her family that her manner was strange at these times she carried on an active business life and never received medical attention.

March 7th, 1931.—Being in the pre-menstrual state she complained of severe headache. Later in the day her relatives hearing a fall found her unconscious on the floor. Seen by her doctor shortly afterwards she was semi-conscious, pale and collapsed. The power of speech was markedly affected, but there were no other paralytic signs. The reflexes were normal, the plantar response was flexor on both sides, the blood pressure was 150/90. A large bruise was present in the lower abdomen. The patient made steady progress and seemed likely to make a complete recovery.

April 1st.—She was getting out of bed and making her speech was improved greatly, but gave the impression that she talked with affectation.

April 2nd.—She complained of severe headache, but as she was again in the pre-menstrual state this was not unusual. She described the headache as being frontal and occipital in distribution. She had been sitting in her bedroom and later in the day she again fell, was found she had vomited and was lying unconscious on the floor. She was removed to a nursing home.

The patient on examination was found to be stuporous and unable to co-operate in any way. She had lost the power of speech and she had a bad right facial palsy. In the central nervous system the outstanding paralytic signs were signs of the right masseter and a right brachial monoplegia. In addition it was noted that the arm reflexes were normal, the legs equal in tone and the reflexes absent, the abdominal reflexes present, the plantar response was on both sides extensor, and ankle clonus was present. Kernig's sign was positive. The optic discs were of normal limits. The signs in the respiratory system suggested that a considerable quantity of vomitus had been inhaled into the right side of the chest. The temperature on admission rose a few hours later to 99.8° F.

In view of the possibility of the condition being due to subarachnoid haemorrhage a lumbar puncture was performed. The cerebro-spinal fluid which was under pressure was uniformly stained with fresh blood and on standing the supernatant fluid was distinctly yellow in colour. These characteristics of the fluid taken in conjunction with the above paralytic signs led to a diagnosis of leaking cerebral aneurysm and such lateralizing signs as there were pointed to the probability that the aneurysm was situated in the left Sylvian artery. On the assumption that the attack of March 7th had a similar origin the yellow staining of the supernatant fluid and the presence of altered blood pigments would be consistent with this explanation.

During the next few days the condition of the patient improved. She was able to understand simple commands but the power of speech and the right brachial monoplegia showed no improvement. The discs remained within normal limits although the veins seemed to be slightly engorged. The pulmonary condition was both slowly progressive and in spite of the condition of the central nervous system becoming more normal the patient died from broncho-pneumonia on April 10th, 1931.

FINDINGS AT NECROPSY

A post-mortem examination of the brain was carried out a few hours after death. There was some fresh blood in the main sulci and about a dessertspoonful round the base of the brain. Over the left Sylvian fissure could be seen a clot of blood about the size of a shilling. Without further examination the brain was allowed to harden in 10 per cent. formol saline. On dissection the circle of Willis was followed out along the left middle cerebral artery which lay in a clot of fresh blood about the size of a walnut. When this was scraped away there was revealed another rugged and more organized clot about a quarter the size of the other—obviously the result of an earlier haemorrhage. This second clot contained a small aneurysm at the origin of one of the branches from the middle cerebral artery. This aneurysm showed slight magnification represented on the Special Plate was spherical in formation and most probably of congenital type. A dissection of the other arteries of the brain showed that they were in a healthy condition and revealed no further aneurysms. In the plane indicated by a post-mortem will be seen in the wall of the aneurysm a small opening (not an artefact) through which the leakage evidently took place.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

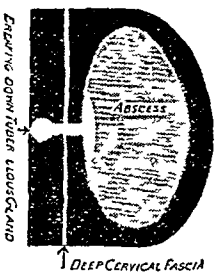
A CONTRACEPTIVE

(*From Special Part*)

It is contended by some birth-control authorities that the absence of a Graafian ring would do all chances of pregnancy except, perhaps, that of extra-uterine gestation on account of the following case may be of interest and some use as a warning.

In February, 1931, Mrs. X, aged 37, married eight years but without children, consulted a London practitioner who as a prophylactic during coitus and was assured that she had a ring inserted into the uterus no other means of contraception were necessary. Under gas and oxygen a ring was inserted and was plainly felt in the uterus and a few days later the patient proceeded to India with her husband. Throughout the year's absence she suffered from irregular menstruation and prolonged menstrual periods. In August and September no periods were seen and there was constant low pain with much more marked pain in the abdomen. There was no vomiting but a constant nausea. The question of pregnancy had never entered her mind nor that of the medical attendant. But as per

cervical abscess To my mind the development of such an abscess while the patient is under observation is a cause for regret, for had the breaking down gland been excised before the fascial erosion the pathological process could have been terminated abruptly Be that as it may no one will question that if the superficial abscess is allowed to break through the skin and a sinus appears this at any rate is an occasion upon which the observer might well say with Whittier, 'What might have been!'



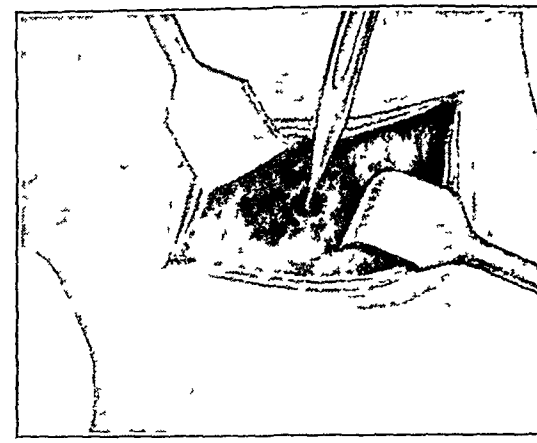


Fig 1

Aspiration of the Superficial Abscess

Repeated aspiration sometimes cures the condition It must be carried out every time the abscess cavity commences to fill event which occurs until the ts of the gland or glands below extruded During this variable patient to be placed in the best ight is the most important of der constant observation (prefer- ition through healthy skin at one the oblique method of Calot has It must be admitted however that low and rather uncertain As I have seen is far from successful In one patient the needle has been introduced directly and the puncture hole is leaking In another the abscess has refilled more quickly than anticipated and the unobservant sufferer has failed to report the matter before the appointed day In a third the patient thinks he has knocked his neck At all events, the very thing which it has been the clinician's object to avoid is present—namely a patch of skin over the centre of the swelling sodden reddened and threatening to break down (Fig 2 on Plate) It was in cases such as these that I first employed collar stud excision—which merely scraping out but completely excising the diseased group of glands beneath the deep fascia

Excision of the Collar Stud

An oblique transverse incision is made over the swelling should there be a small area of unhealthy skin near the proposed line of incision this is excised elliptically To the skin edges moist gauze pads are accurately attached The anterior border of the sterno mastoid is now defined Special attention is directed to the character of this muscle for the following reason if it is flattened out over the swelling it is highly probable—in my experience certain—that one is dealing not with a tuberculous abscess but with an inflamed branchial cyst Even after the special trouble which I take to exclude the latter condition it was on three occasions only the sign of muscle flattening at this stage which indicated the true nature of the swelling These *diagnostic* humiliations were due to therapeutic aspiration which robs the branchial fluid of its characteristic cholesterol In one case tubercle bacilli as well were demonstrated in the fluid In collar stud abscess the exposed sterno mastoid feels stiffened and somewhat thicker than normal With a little dissection in front of this structure the abscess is opened and pale yellow pus exudes The cavity is emptied and mopped dry and as one peers within a lining of soft dark red granulations called Volkmann's membrane is seen Here and there some inspissated material clings to the walls and cannot be wiped away These patches are dissected off and in the same way the sterno mastoid is cleaned until the whole cavity presents an even reddish hue A Watson Cheyne seeker is employed to find the tiny opening in the deep fascia as shown in the drawing reproduced below The opening is enlarged by stretching and the finger explores beneath By this method the diseased glands which up to this time are not at all apparent can soon be found One now settles down to a careful dissection ligaturing

[illegible]
(Late Surgeon RN)

The patient a single woman aged 41 was admitted into [illegible] hospital suffering from [illegible] an operation of the [illegible] the right side [illegible] to effect a cure. Since October 1928 she had complained of a constant [illegible] pain over the right eye which was to a large degree relieved by the administration of aspirin. She was [illegible] but the family history revealed nothing of importance. At these times she showed no definite [illegible] and [illegible] normal arteries

March 7th 1931—Being in the premenstrual state she complained of severe headache. Lying in the dark her head was [illegible] against a tall [illegible] and her temperature was 98 The first [illegible] but the [illegible] was subsequently [illegible] pale and collapsed. The [illegible] of speech was marked although there were no other gross signs. The reflexes were normal the plantar response was flexor on both sides the optic fundi were [illegible] a large [illegible] was present in the [illegible] The patient made steady progress and [illegible] home to make a complete recovery

April 1st—She was getting out of bed and walking but speech had improved greatly but [illegible] was [illegible] that she [illegible] with [illegible]

April 2nd—She complained of severe headache but as she was [illegible] the previous normal state the [illegible] normal She described the headache as being frontal and central in distribution She had been sitting in her bedroom and later in the day she [illegible] and had [illegible] and was [illegible] On the first She was removed to a nursing home

The patient on examination was found to be [illegible] and [illegible] [illegible] She had [illegible] the power of speech and the [illegible] with the left hand In the cranial nerves [illegible] the [illegible] pupil signs were regular of the [illegible] and [illegible] normal In addition it was noted that the arm reflexes were normal the [illegible] equal on the [illegible] was absent the [illegible] present the plantar [illegible] on both sides and all abdominal reflexes absent Kernig's sign was present The optic [illegible] were normal Lumbar The state of the [illegible] system suggested that a considerable [illegible] of [illegible] and [illegible] had [illegible] the right side of the chest The [illegible] lumbar being abnormal [illegible] a [illegible] brain [illegible] [illegible]

In view of the possibility of the condition being due to subarachnoid haemorrhage a lumbar puncture was performed The cerebrospinal fluid which was under pressure was [illegible] and with [illegible] blood after standing the supernatant fluid was distinctly yellow in colour These characteristics of the fluid taken in connection with the above general symptoms led to a diagnosis of leaking cerebral aneurysm and such localising signs as to be were pointed to the probability that the aneurysm was situated in the left Sylvian [illegible] On the assumption that the attack of March 7th had a similar cause the [illegible] staining of the supernatant fluid indicative of altered blood pigments would be consistent with this explanation

During the next few days the condition of the patient improved [illegible] she was able to understand simple commands but the power of speech and the right brachial monoplegia showed no improvement The optic remained within normal limits although the [illegible] was slightly raised The [illegible] reaction was somewhat progressive and in spite of the occasional [illegible] the central nervous system [illegible] more normal the patient died from [illegible] on April 10th 1931

Post-mortem Notes.

A post-mortem examination of the brain was carried out a few hours after death There was some fresh blood in the [illegible] and over a [illegible] round the base of the brain On the left Sylvian artery could be seen a clot of blood about the size of a shilling Without further examination the brain was allowed to harden in 10 per cent formol saline On dissection the circle of Willis was opened out and the left middle cerebral artery was found to contain a clot of fresh blood about the size of a walnut When this was scraped away there was revealed a small [illegible] and more proximal clot about a quarter the size of the other [illegible] the result of an earlier haemorrhage This second clot surrounded a small aneurysm at the point of origin of the striates from the middle cerebral artery The aneurysm above clearly measured [illegible] on the Sylvian Plate was [illegible] in outline and was [illegible] of [illegible] type A dissection of the other arteries of the brain showed that there was a [illegible] [illegible] and [illegible] no further aneurysms In the [illegible] caused by a [illegible] will be seen in the wall of the aneurysm a small opening [illegible] an attempt [illegible] made the leakage evidently took place

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

A CONTRACEPTIVE

(By a Special Pleader)

It is contended by some [illegible] authorities that the insertion of a Gräfenberg ring precludes all chance of pregnancy except perhaps that of extra-uterine gestation on account of the following case may be of interest and a [illegible] a number

In February 1931 Mrs X aged 36 married eight years but with no children consulted a London physician with a [illegible] of birth control and was assured that a [illegible] ring inserted into the uterus no other means of contraception [illegible] be necessary Under gas and oxygen a full-size Gräfenberg ring was placed in the uterus and a few weeks later the patient proceeded to India with her husband The [illegible] the early months of the year she suffered from [illegible] menorrhagia and backache with [illegible] during her menstrual periods In August and September no periods were seen and there was constant [illegible] with much [illegible] a pain in the left iliac fossa There was no vomiting but a constant [illegible] distress The question of pregnancy had not entered her mind nor that of the medical attendant but as her

symptoms increased especially the fever and pain, she was brought down to Calcutta

On examination I found she was about nine to ten weeks pregnant The radiogram by Dr Galstaun (reproduced on the Special Plate) explains itself Because of her symptoms and anaemia I advised that the patient s uterus should be emptied This was done and the ring was found embedded in the chorion presumably responsible for the pain discharge and fever The foetus appeared normal although it is a matter of speculation whether pregnancy to full term without disability to the mother or the foetus could occur in such a case This report and perhaps there are others of like nature unrecorded will perhaps curb enthusiasm

SUDDEN DEATH FROM HAEMORRHAGE INTO THE SUPRARENAL CAPSULES IN A CHILD

(With Special Plate)

According to certain observers haemorrhage into the suprarenal capsules is extremely common in infancy Histologically haemorrhage into the suprarenal capsules can be demonstrated in nearly all newborn infants (Grulee s *Clinical Pediatrics*) Toxaemia and injury, particularly if there is asphyxia as in difficult and prolonged labour is the predisposing cause in most of the cases There is however a type in which there is no history of injury at birth or otherwise in which the 'apparently normal child goes into collapse and dies as in the case about to be described Thomson (*Diseases of Children*) says

> The most interesting type of the disease is that which occasionally sets in in children during the first year of life as part of a rapidly fatal illness The symptoms set in suddenly with severe abdominal pain high fever and sometimes vomiting and diarrhoea Scattered spots may appear over the surface of the body Convulsions are common and death may occur within twenty four hours

The following case belongs to this latter type although it differs from Thomson s description in that the child showed practically no symptoms previous to death

A female child about 7 months old was brought to the surgery by its father in the middle of the night On examination the child was dead having died in its father s arms on the way a matter of less than five minutes walk The most obvious thing noticed was a cluster of purpuric spots about the size of half a crown on the left cheek while all over the surface of the body on the buccal mucous membrane and soft palate were scattered discrete spots of the same type The child was rather poorly nourished and flabby but no evidence of rickets or other gross disease was observed

The story told by the father was that the child had been in its usual health until the day previous when it had been off colour and had vomited once The condition of the child at bedtime was not such as to cause the parents to seek medical advice During the night the mother s attention was called by the child s making a funny noise and when the light was turned on she noticed it was black in the face That appearance was due partly to the purpuric rash there was no question of asphyxia Thereupon the child was immediately brought to the surgery

Post mortem examination showed a poorly nourished underdeveloped child with purpuric spots as described Thorax abdomen brain and meninges disclosed nothing abnormal except that there were recent extensive haemorrhages in both suprarenal capsules as shown in the Plate

This case showed none of the several constitutional symptoms usually described It was the type that suddenly went into collapse and died The condition seems sufficiently rare to merit description

Derby F Pettigrew M B Ch B

ARTERIO VENOUS ANEURYSM OF THE LEFT SUPERFICIAL TEMPORAL VEIN

(With Special Plate)

A Somali male aged about 35 came to hospital and gave the following history

As a result of a fight he was struck by a thick stick in front of the left ear two or three years previously There was much swelling and pain at the site of the injury but practically no bleeding At first he maintained that there was no bleeding at all but eventually acknowledged that there might have been not more than a tablespoonful After a week or two the swelling subsided completely except for a small pulsating area exactly where he was hit This then gradually extended over the scalp until the condition seen on admission was brought about

On admission he complained of throbbing and headache, especially in the occipital region

On examination there was a small scar about half an inch long at the site of the original injury and an obvious arterio venous aneurysm of the left superficial temporal vein and its anterior and posterior tributaries The photograph shows the condition fairly well The superficial temporal and posterior temporal veins were enlarged to two fingerbreadths and very tortuous At the site of anastomosis with the occipital vein the swelling was more saccular and the skull could be felt to be eroded beneath it—a depression about one inch in diameter The anterior temporal vein was less enlarged and gradually dwindled away towards the root of the nose The transverse facial vein was unaffected Pulsation was marked and a systolic thrill and a systolic bruit could be made out over the whole aneurysm Firm pressure in front of the ear allowed the veins to empty completely

Operation —An incision was made in front of the ear over the proximal portion of the aneurysm, and an attempt was made to dissect it out with a view to ligaturing the superficial temporal artery where it communicated with the aneurysm This could not be done owing to the thinness of the walls of the aneurysm and to the fact that it was adherent to the parotid fascia and zygoma completely covering the artery A small incision was therefore made about two inches higher up at the point marked L in the photograph and a ligature was applied there After operation the distal portion of the aneurysm disappeared entirely after a short rise of temperature accompanied by pain and tenderness a week later due to thrombosis taking place in it The portion proximal to the ligature slowly hardened and it now remains four months after operation as a smallish hard lump in front of the ear with pulsation just perceptible in it The headache giddiness, and throbbing have entirely disappeared

Commentary

The interesting points in this case seem to be (*a*) the fact that the condition was brought about not by a penetrating wound but by a crushing of the vessels against the zygoma—as shown by the nature of the injury and the small amount of external bleeding and (*b*) the considerable area of bone erosion in the occipital region and the pain produced thereby in spite of the fact that the occipito frontalis muscle lies between the vessels and the bone

STERNAL FISSURE IN A CHINESE

(With Special Plate)

A Chinese boy 17 years of age came to the hospital complaining of occasional swelling of the feet this year (1931) When he was undressed it was at once obvious that he had a deep fissure of the sternum at the bottom of which the aorta could be seen to pulsate On inquiry he said that he had had this condition since birth At the bottom of the depression there was a small scar for which he could not account but which had probably been caused by needling by the native method Previous

illnesses and no history of tuberculosis. He has always been strong and during this year had come nothing but rest at home. There was a slight cough but he said he had no sputum.

Examination showed that the patient was a healthy-looking man with the exception of the right upper limb. On the right side of the chest there was marked wasting of the pectoral muscles and the right shoulder was somewhat depressed. The muscles could be felt to contract on the slightest effort, but there was no general tremor. The scapula and clavicle moved more or less normally during movements of the arm, but there was obvious limitation of movement at the shoulder joint. The head of the humerus could not be made out. The range of movement in the shoulder joint was very limited, but there was no pain or tenderness on manipulation. There was no evidence of tuberculosis elsewhere in the body. The heart and lungs were normal. The blood pressure was 120/80. The urine was normal. The Wassermann reaction of the blood was negative. The sputum was examined on three occasions and found to be free from tubercle bacilli. The radiograph showed the condition of the shoulder joint and a portion of the upper end of the humerus. There was no evidence of tuberculosis elsewhere in the body.

The interesting features of this case are: (1) that although on first examination the muscles of the deltoid region appeared to be extended at each end they were found to be fixed; (2) there was a primary extension of the arm during the examination.

I am indebted to Mr. [illegible] Brown, surgeon to the Queen Charlotte's Hospital, for permission to publish this case.

HERPES ZOSTER WITH FACIAL PARALYSIS: CHICKEN-POX IN SAME HOUSEHOLD

On September 21st I attended a boy aged 13 years who complained of intense pain behind the right ear. Examination revealed a crop of vesicles over the mastoid region and the case was diagnosed as herpes zoster. On the next but two days later the patient was observed to have marked complete facial paralysis on the same side as the herpes. There was no other sign of involvement of the nervous system. When I saw the herpes had disappeared but the facial paralysis persisted. An additional point of interest is that the patient's two grandchildren, living in the same house, developed chicken-pox on September 17th, a fortnight after the grandfather's herpes began. There were no other cases of chicken-pox reported in the district. The herpes patient has been almost completely deaf in both ears for the last ten years. We know that the facial nerve sends a posterior auricular branch behind the ear, but this has not been proved to contain secretory fibres. The present case may account for this area coming from perineal nerves. Cases may be recorded in which herpes zoster has occurred in the neighbourhood of the external auditory meatus together with facial paralysis of the same side. I am not aware of a herpes zoster of the ear complicated by facial paralysis.

[illegible] G. H. H. BOOTH, M.B., Ch.B.

BREECH PRESENTATION

In view of the recent discussion on breech presentation which has been carried on in the *British Medical Journal*, the following case which occurred in Queen Charlotte's Hospital may be worth recording.

A primipara aged 18 was admitted on October 7th, 1931, in labour. She was a breech presentation with both legs and each arm extended. On October 7th version and extraction was attempted unsuccessfully. The patient continued in labour and was allowed to go on to labour spontaneously. Pains began at 1 a.m. on November 10th and the patient was admitted at 4.30 a.m. On examination the cervix was found to be the size of a shilling, membranes intact. At 10 a.m. the membranes ruptured spontaneously at 11.5 a.m. under general anæsthesia in the dorsal position a hand was found and both legs and the arm were delivered. The cervix was sufficiently dilated and the head brought down with a pair of Bland-Sutton's vectis applied over the occiput. The head was delivered with forceps and secondary traction. There was no excess of liquor amnii and the baby breathed at once.

The interesting features of this case are: (1) that although on first examination the muscles of the deltoid region appeared to be extended at each end they were found to be fixed; (2) there was a primary extension of the arm during the examination.

I am indebted to Mr. [illegible] Brown, surgeon to the Queen Charlotte's Hospital, for permission to publish this case.

CLINICAL AND SCIENTIFIC PROCEEDINGS

SOUTH MIDDLESEX DIVISION

Meeting at the Hall

At a meeting of the South Middlesex Division on November 25th with the chairman Dr. L. H. F. Walton presiding, Mr. Graham Mason delivered an address on minor injuries of the hand, including burns and scalds.

Mr. Mason said that in the case of incised wounds causing cut of more of the palmar digital tendons of the hand or fingers it was important to bear in mind the relationship of the synovial sheaths to a straight stiff finger was the result. The first action of the surgeon depended upon preserving the integrity of the parietal sheath between the two layers of the synovial or mucous sheath and the prevention of adhesions here. Suture was often difficult and should be performed as soon as possible after the accident. Following closure of the wound the part should be splinted in the position of least tension and movement be prohibited for two or three weeks. It was important to avoid causing the severed ends of the tendon and to unite them as early as possible with the adjacent structures. In long immobilization of the hand as also in cases of Colles's fracture the interphalangeal and metacarpophalangeal joints became progressively stiff. The contractures were unusually resistant to treatment and the sufferer after a few weeks of inaction might require many months of treatment. Active movement of the adjacent joints should therefore be started as soon as possible. The extensor tendons however from the base of the first phalanx downwards were devoid of synovial covering and on the dorsum of the fingers the tendon spread out into a broad fixed expansion division of which was not allowed by retraction on the splinting in a position of hyperextension had therefore to be maintained. Traumatic arthritis of an interphalangeal joint might be followed by long-lasting stiffness, pain and swelling. X-ray examination usually revealed no abnormality and the underlying factor being bruising of the articular cartilage. The best method of treatment was the application of hot gentle massage and movement. Fractures of the metacarpal bones were not as a rule accompanied

symptoms increased especially the fever and pain she was brought down to Calcutta

On examination I found she was about nine to ten weeks pregnant The radiogram by Dr Galstaun (reproduced on the Special Plate) explains itself Because of her symptoms and anaemia I advised that the patient s uterus should be emptied This was done and the ring was found embedded in the chorion presumably responsible for the pain discharge and fever The foetus appeared normal, although it is a matter of speculation whether pregnancy to full term without disability to the mother or the foetus could occur in such a case This report and perhaps there are others of like nature unrecorded, will perhaps curb enthusiasm

STERNAL FISSURE IN A CHINESE

(With Special Plate)

A Chinese boy 17 years of age came to the hospital complaining of occasional swelling of the feet this year (1931) When he was undressed it was at once obvious that he had a deep fissure of the sternum at the bottom of which the aorta could be seen to pulsate On inquiry he said that he had had this condition since birth At the bottom of the depression there was a small scar for which he could not account, but which had probably been caused by needling by the native method Previous

illnesses had no bearing on his condition. He has never been strong, and during this year had come nothing but rest at home. There was a slight cough, but he said he had no sputum.

Examination showed that the upper four sternebræ were separated by a complete fissure 1 mile from the manubrium downwards; there was normal union through the bone ridge was somewhat depressed. The unjoined sternal portions lined the sides of the deep depression, their lower ends in the central line. The sterno-hyoid and sterno-thyroid muscles arose from the edges of these plates about three inches below the normally developed clavicle. The sternal head of the sterno-mastoid muscle could not be made out. The skin at the bottom of the depression lay directly on the first part of the aorta and the upper part of the heart, and it pulsated violently with the movements of the heart.

Antero-posterior x-ray films showed the heart to be about normal in size and position, though slightly raised. The diaphragm was also more dome-shaped than is usual. No bony sequestra could be made out in the sternal plates. The rib cartilages sprang from the ribs at the usual sites.

The patient refused the offer of a restorative operation, and the matter was not pressed. The interesting point is the disability arising from the fact that the framework of the chest is not properly closed. The area which lies bare is depressed by inspiration, and by so much defeats the muscular efforts to produce a negative pressure in the thoracic cavity. The patient has rounded shoulders, produced in an effort of nature to reduce the gap. There is no other physical condition to account for the failure of the heart to meet the demands of normal exercise and work. The pulse-rate was about 80 per minute, and there was no dyspnœa while at rest. He was advised to take up sedentary work.

School's Memorial Hospital, Shanghai.

HERPES ZOSTER WITH FACIAL PARALYSIS: CHICKEN-POX IN SAME HOUSEHOLD

On September 3rd I attended an old lady, aged 73 years, who complained of intense pain behind the right ear. Examination revealed a crop of vesicles over the mastoid region, and the case was diagnosed as herpes zoster. On my next visit two days later the patient had developed a well-marked complete facial paralysis on the same side as the herpes. There was no other sign of involvement of the nervous system. Within a week the herpes had disappeared, but the facial paralysis persists. An additional point of interest is that the patient's two grandchildren, living in the same house, developed chicken-pox on September 17th, a fortnight after the grandmother's herpes began. There were no other cases of chicken-pox reported in the district. The herpes patient has been almost completely deaf in both ears for the last ten years. We know that the facial nerve sends a posterior auricular branch behind the ear, but this has not been proved to contain sensory fibres. The sensory distribution for this area comes from cervical nerves. Cases have been described in which herpes zoster has occurred in the neighbourhood of the external auditory meatus, together with facial palsy of the same side. I am not aware of a herpes *behind* the ear complicated by facial paralysis.

Heath's Range, N. G. H. BOOTH, M.B., Ch.B.

BREECH PRESENTATION

In view of the recent discussion on breech presentation which has been carried on in the *British Medical Journal*, the following case, which occurred in Queen Charlotte's Hospital, may be worth recording.

A primigravida, aged 18, was admitted on October 2nd, 1931, and remained at the Hospital for a breech presentation. The report on the x-ray picture was:

Breech presentation with both legs and one arm extended. On October 7th version without anæsthesia was attempted unsuccessfully. The patient continued to attend antenatal and was allowed to go into labour spontaneously. Pains began at 1 a.m. on November 10th, and the patient was admitted at 8.30 a.m. On examination the cervix was dilated to the size of a shilling, membranes intact. At 10 a.m. the membranes ruptured spontaneously. At 11.45 a.m. under general anæsthesia in the dorsal position a hand was introduced into the vagina, and both legs and one arm were felt flexed. The cervix was fully dilated, and the feet brought down. When the body had been born to the costal margin a hand was again passed up, and both arms, which were flexed over the chest, were delivered. The head was delivered by jaw flexion and shoulder traction. There was no excess of liquor amnii, and the baby weighed 7 lb.

The interesting features of this case are (1) that although on x-ray examination five weeks before delivery the legs were found to be extended at delivery they were found to be flexed; (2) there was a primary extension of one arm shown by x-ray examination.

I am indebted to Mr. Alec Bourne, senior obstetric surgeon to Queen Charlotte's Hospital, for permission to publish the case.

CLINICAL AND SCIENTIFIC PROCEEDINGS

SOUTH MIDDLESEX DIVISION

Minor Injuries of the Hand

At a meeting of the South Middlesex Division on November 26th, with the chairman, Dr. L. H. F. WALTON, presiding, Mr. GRANT MASSIE delivered an address on minor injuries of the hand, including burns and whitlows.

Mr. Massie said that in the case of incised wounds dividing one or more of the palmar flexor tendons of the hand or fingers it was important to bear in mind the relationship of the synovial sheaths if a straight stiff finger was not to result. The free action of the tendon depended upon preserving the integrity of the potential space between the two layers of the synovial or mucous sheath, and the prevention of adhesions here. Suture was often difficult, and should be performed as soon as possible after the accident. Following closure of the wound the part should be splinted in the position of least tension, and movement be prohibited for two or three weeks. It was important to avoid bruising the severed ends of the tendon, and to interfere as little as possible with the adjacent structures. In long immobilization of the hand, as also in cases of Colles's fracture, the interphalangeal and metacarpo-phalangeal joints became progressively stiff. The contractures were unusually resistant to treatment, and the stiffness after a few weeks of fixation might require many months of treatment. Active movement of the adjacent parts should therefore be started as soon as possible. The expansor tendons, however, from the bases of the metacarpals downwards were devoid of synovial covering, and on the dorsum of the fingers the tendon spread out into a firmly fixed expansion, division of which was not followed by retraction; simple splinting in a position of hyperextension led therefore to rapid union. Traumatic arthritis of an interphalangeal joint might be followed by long-lasting stiffness, pain, and swelling. X-ray examination usually revealed no abnormality, and the thickening was manifestly paraarticular, the underlying factor being bruising of the articular cartilage. The best method of treatment was the application of near, gentle massage and movement. Fractures of the metacarpal bones were not as a rule accompanied

by much displacement and the normal concavity of the hand could be maintained by the application of a tennis ball splint reunion occurring in three or four weeks Fracture of the scaphoid did not always result in failure of union but immobilization for three to six months was necessary the most generally favoured method being encasement of the wrist in plaster, with the joint fixed in the dorsiflexed position, the hand slightly adducted and the fingers left free to move Such fixation would largely obviate the excavation of the bone which complicated non union and would prevent the disability of mechanical arthritis Removal of part or the whole of the fractured bone was disappointing and immobilization should first be tried even when the patient began treatment long after the original injury A dislocated semilunar bone should be removed since if the condition was allowed to persist the median nerve might be seriously compressed

Infections of the terminal phalanges might lead to necrosis since the distal blood supply was through the finger pulp A tourniquet should always be used for unless the individual structures were recognized the pus might not be detected and further extension of the sepsis might be promoted by the indiscriminate opening of uninfected spaces Rubber dam was the most suitable material for drainage and tubes should never be used Swelling of the dorsum being nearly always a secondary condition should not be opened In infections of the tendon sheaths Kanavel's technique had proved eminently satisfactory and the early restoration of function after drainage was of the utmost importance The early recognition of acute lymphangitis was essential since inopportune surgery might endanger the patient's life unless a local abscess developed in the lymphatic glands at the elbow or axilla surgical intervention was definitely harmful The employment of anti streptococcal serum and S U P 36 had not proved successful

The pyrexia of uninfected burns was due to the action of certain toxic bodies on the thermal heat centre The subnormal temperature convulsions delirium and coma which might appear as late as a week or twelve days after the burn had been attributed to protein shock In all cases the degree of primary shock should be ascertained and measures for relief be instituted such as morphine injections the electric light cradle and the intravenous administration of saline solution or glucose Immersion in a hot saline bath (110° F.) allowed the clothing to be removed without unnecessary injury to the painful areas and restored the body temperature to normal The exsanguination transfusion treatment of Robertson and Boyd had not been widely practised in this country even though there was some support for the view that the circulating toxin was carried by the erythrocytes One of the most important contributions to the treatment of burns was the tannic acid method formulated by E C Davidson of Detroit in 1925 The burned areas were covered by dry sterile gauze pads held in place by sterile gauze bandages and this dressing was then soaked in a 2½ per cent aqueous solution of tannic acid It must be freshly prepared before use It was more usual now to spray the burned areas with an atomizer at half hourly intervals until the surface became mahogany red in colour Extensive burns were coagulated in about sixteen hours but if the deeper layers were involved twenty four hours might elapse before the process of hardening was complete Exposure to air accelerated the tanning process and heat hastened the drying of the coagulum This method of spraying was particularly useful in burns about the face ears nose and mouth Tannic acid generally relieved the burning pain within half an hour of its application and prevented in some measure the absorption of toxins from the necrotic material Davidson had found that the application of moist boric acid dressings to the tanned area resulted immediately in the appearance of toxic symptoms The waterproof coagulum prevented the further loss of tissue fluid The dry, non absorptive covering of protein tannate protected the nerve endings and enabled the new epithelium to re form beneath it without necessitating daily dressings The resulting scar tissue was undoubtedly less marked than after any other method of treatment

Reports of Societies

NORMAL DEVELOPMENT IN THE YOUNG CHILD

At the December dinner meeting of the West London Medico Chirurgical Society a discussion took place on normal development in the infant and the young child Dr H H MILLS presided

Dr SIDNEY OWEN in opening contented himself with putting to the members a series of questions He asked why it was that so many premature infants faded away Was it because they were not given sufficient food? If so what amount of food should be given and how often should a premature baby be fed? What was the opinion with regard to breast feeding in the case of a mother suffering from chronic heart disease or lung trouble? Did the breast fed infant eventually reach adult life in a more healthy condition than an infant who had been bottle fed? Were not many failures attributed to patent foods due in the main to the fact that these foods were not suitably modified? Did the boiling and sterilizing of raw milk make it a really suitable food for infants? Turning to the question of sleep Dr Owen asked whether the nervous tired child was a product of recent times or had it always existed in one form or another? What advice was commonly given to a parent who complained that her baby would not sleep? As to rickets he did not believe that the last word had been said Could it be guaranteed that a child would never show signs of the disease even when it had been brought up in the most modern conditions which aimed at prevention? Finally what part did the clothing play in the development of the infant?

Professor H A HARRIS showed a series of lantern slides illustrating the growth laws of the bony nervous lymphoid genital and other systems He considered that it was a mistake to speak of any particular build of the body as essential to health Almost any build was compatible with a healthy life The foundations of teeth structure were determined long before the proportion of vitamins in the food could have any effect and a well-fed mother probably accounted for much more in the dental well being of her offspring than the child's absorption of vitamin D Dr VAUGHAN PENDRED strongly advocated cow's milk undiluted with water as a diet for the young child Another rule which ought to be observed was to insist upon a period of sleep or repose after feeding Dr BERNARD MYERS said that the ideal food for the infant was human milk, in the absence of that he would continue to use a certain mixture of milk and water and carbohydrates He had even found full cream condensed milk useful at times Dr JAMES FENTON (M O H Kensington) said that during the past ten or twelve years London milk had been pasteurized Had surgeons noticed during that period a positive decline in gland and joint tuberculosis? Dr A M COOKE on the subject of pasteurized milk said that he had recently seen a man of 55 suffering from gross scurvy the man had been living on shredded wheat and on the milk supplied by a well known London dairy The condition cleared up after the administration of vitamin D

Dr. RONALD CASTLE said that clinicians often did not understand the technique of breast-feeding. Many children were put off the breast because they were said to have constipation which on examination was found not to exist at all. We had not yet got clean milk in this country, and this would not come about until pasteurization was compulsory. Pasteurized milk was excellent if the process was properly carried out. Dr. J. F. HALLS DALLY said that pasteurization in big cities was more or less a necessity, though a pasteurized milk did not necessarily mean a clean milk. Dr. KINGSTON BROWN agreed with other speakers in emphasizing the importance of cow's milk provided it could be obtained pure and he believed that Grade A was in any case better than pasteurized milk in this respect. In his early practice he invariably found that the children who had perfect teeth had been breast-fed. The next best teeth were seen in children who had had cow's milk, while rickety teeth occurred in children fed on patent foods. Dr. GERALD SLOT commented upon the amount of sleep lost by young children in working-class homes owing to conditions of overcrowding and to the disturbance caused by the wireless. Dr. MARCUS found on some psychological problems affecting the child's mother, such as those resulting from the arrival of a new baby. Dr. MARGARET LOVEWELL found some psychological difference between breast-fed and bottle-fed children. The latter seemed more predisposed to psychological trauma. Dr. WHITEHOUSE HOWELL speaking as an orthopædic surgeon said that rickets and deformities were still very much in evidence and pleaded for more team work in the elucidation of the rickets problem.

Dr. H. H. MILLS in summing up the discussion drew attention to the way in which clinicians could help the nursing mother who was beginning to be fatigued by making the child feed at four-hour intervals instead of at shorter periods, and when breast-feeding was beginning to fail by supplementing with cow's milk and other foods.

INTRA-THORACIC NEW GROWTHS

At the December meeting of the Liverpool Medical Institution with the president Professor W. BLAIR-BELL in the chair, Dr. LESLIE CUNNINGHAM read a paper on Intra-thoracic new growths.

He said that the majority of cases of intra-thoracic tumour were carcinomata arising in the œsophagus. One case of sarcoma occurred in a series of seventeen primary growths, the remainder were mainly cases of carcinomata. These were subdivided into cases with (1) evidence of pleural effusion, (2) hæmoptysis, (3) evidence of localized infection of the lung, and (4) a variety of symptoms in which the diagnosis was not obvious on examination. Pain was a frequent feature, and the majority of the cases with pain eventually developed evidence of pleural involvement. Bosworth's sign of supraclavicular retraction was seen in some cases and constituted an interesting sign. Dr. CUNNINGHAM showed radiograms illustrating various cases particularly with reference to the differential diagnosis. One case closely resembled a primary growth but exploration showed it to be a sarcoma. Of those with secondary deposits in the lungs a large proportion of cases showed carcinoma of the breast. In these pleural involvement was the rule. One showed definite malignant cells in the effusion while the x-rays findings were negative.

The speaker said that intra-thoracic new growths were a difficult problem to surgeons, and he pleaded for more careful study than was accorded to it by the physicians of the day. The one most prominent symptom which was common was complete exhaustion. Certain manifestations of malignant disease in the lungs were sufficiently definite to call for a diagnosis at a tolerably early stage. Dullness with silence and paralysis of the left recurrent laryngeal nerve were signs which, even in the absence of other phenomena, should be regarded with the gravest suspicion.

In the discussion that followed the PRESIDENT said that lead therapy had been withheld in such cases owing to the belief that massive necrosis might occur. Only few had been so treated. He recalled, however, at least one case in which life had been greatly prolonged. He thought that, with the better preparations and methods now employed, it would be worth while considering the possibilities of lead therapy again, for there seemed otherwise to be no hope for these patients.

Mr. JOHN T. MORRISON urged that there was great need for still earlier diagnosis. Even in the case of tumours acknowledged to be malignant he pleaded for a more optimistic outlook. Radium treatment was still in its infancy; actual resection of such tumours was known to have resulted in cure in a few reported cases, and in certain cases of supposed unresolved pneumonia surgery alone could elucidate the diagnosis. For these reasons still earlier recourse should be had to the radiologist, and the surgeon should be called in to complete the team. Dr. CHAMBERLAIN spoke of the difficulty in the diagnosis of pulmonary neoplasms from inflammatory lesions, especially low grade types of pneumonia with purulent infiltration. Dr. T. B. DAVIE referred to the histological basis of the types of bronchial carcinoma described and stressed the fact that all these types were often represented in the same tumour. In most cases of oat-cell carcinoma, if sufficient blocks were cut from different parts of the tumour, some sections would reveal the presence of epithelioma with typical cell nests.

In a discussion arising from a note read by Dr. S. B. HEAD on two cases of attempted abortion the PRESIDENT called attention to the condition of pseudo-pregnancy. There was generally the fear of pregnancy with amenorrhœa. In these cases the corpus luteum of the preceding menstruation was persistent and large. Attempted abortion in such circumstances had come within Professor Blair-Bell's own experience, and the absence of pregnancy altered the medico-legal aspects of the case. He agreed that it was difficult always to believe that a woman, especially when nulliparous, could herself pass an instrument through the os uteri. He generally suspected that she was shielding someone else by her statement. He considered that all cases in which the practitioner was in doubt as to the correct course to pursue he should report the matter to the medical officer of health and throw the responsibility of action on him.

Dr. GLYNN WHITE read a paper on the present treatment of cancer.

TRANSPLANTATION OF FIBULA

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland with the president Mr. R. ARMISTEAD STONEY in the chair, Mr. F. GILL read notes on a case of transplantation of the fibula.

The patient, a girl aged 10, was admitted to hospital on November 27th, 1928, with a history of pain and swelling of the left thigh about one year previously. An operation had been performed in the country and she had attended a hospital for dressing of a sinus. On examination there was a [illegible] sinus [illegible] on the anterior aspect of the left thigh. There was loss of the greater portion of the shaft of the tibia and two discharging sinuses, one from the upper and one from the lower portion of the tibia. A skiagram was made on which two areas of rarefying [illegible] in the leg and marked muscular wasting of the thigh and calf. A skiagram showed an abscess cavity with a small sequestrum in the upper part of the tibia and a similar

by much displacement and the normal concavity of the hand could be maintained by the application of a tennis ball splint, reunion occurring in three or four weeks. Fracture of the scaphoid did not always result in failure of union but immobilization for three to six months was necessary, the most generally favoured method being encasement of the wrist in plaster with the joint fixed in the dorsiflexed position, the hand slightly adducted and the fingers left free to move. Such fixation would largely obviate the excavation of the bone which complicated non-union and would prevent the disability of mechanical arthritis. Removal of part or the whole of the fractured bone was disappointing and immobilization should first be tried even when the patient began treatment long after the original injury. A dislocated semilunar bone should be removed since if the condition was allowed to persist the median nerve might be seriously compressed.

Infections of the terminal phalanges might lead to necrosis since the distal blood supply was through the finger pulp. A tourniquet should always be used for unless the individual structures were recognized the pus might not be detected and further extension of the sepsis might be promoted by the indiscriminate opening of uninfected spaces. Rubber dam was the most suitable material for drainage and tubes should never be used. Swelling of the dorsum being nearly always a secondary condition should not be opened. In infections of the tendon sheaths Kanavel's technique had proved eminently satisfactory and the early restoration of function after drainage was of the utmost importance. The early recognition of acute lymphangitis was essential since inopportune surgery might endanger the patient's life unless a local abscess developed in the lymphatic glands at the elbow or axilla surgical intervention was definitely harmful. The employment of anti-streptococcal serum and S.U.P. 36 had not proved successful.

The pyrexia of uninfected burns was due to the action of certain toxic bodies on the thermal heat centre. The subnormal temperature convulsions delirium and coma which might appear as late as a week or twelve days after the burn had been attributed to protein shock. In all cases the degree of primary shock should be ascertained and measures for relief be instituted such as morphine injections the electric light cradle and the intravenous administration of saline solution or glucose. Immersion in a hot saline bath (110° F.) allowed the clothing to be removed without unnecessary injury to the painful areas and restored the body temperature to normal. The exsanguination transfusion treatment of Robertson and Boyd had not been widely practised in this country, even though there was some support for the view that the circulating toxin was carried by the erythrocytes. One of the most important contributions to the treatment of burns was the tannic acid method formulated by E. C. Davidson of Detroit in 1925. The burned areas were covered by dry sterile gauze pads held in place by sterile gauze bandages and this dressing was then soaked in a 2½ per cent. aqueous solution of tannic acid. It must be freshly prepared before use. It was more usual now to spray the burned areas with an atomizer at half-hourly intervals until the surface became mahogany-red in colour. Extensive burns were coagulated in about sixteen hours but if the deeper layers were involved twenty-four hours might elapse before the process of hardening was complete. Exposure to air accelerated the tanning process and heat hastened the drying of the coagulum. This method of spraying was particularly useful in burns about the face ears nose and mouth. Tannic acid generally relieved the burning pain within half an hour of its application and prevented in some measure the absorption of toxins from the necrotic material. Davidson had found that the application of moist boric acid dressings to the tanned area resulted immediately in the appearance of toxic symptoms. The waterproof coagulum prevented the further loss of tissue fluid. The dry non-absorptive covering of protein tannate protected the nerve endings and enabled the new epithelium to re-form beneath it without necessitating daily dressings. The resulting scar tissue was undoubtedly less marked than after any other method of treatment.

Reports of Societies

NORMAL DEVELOPMENT IN THE YOUNG CHILD

At the December dinner meeting of the West London Medico-Chirurgical Society a discussion took place on normal development in the infant and the young child. Dr. H. H. MILLS presided.

Dr. SIDNEY OWEN in opening contented himself with putting to the members a series of questions. He asked why it was that so many premature infants faded away. Was it because they were not given sufficient food? If so what amount of food should be given and how often should a premature baby be fed? What was the opinion with regard to breast-feeding in the case of a mother suffering from chronic heart disease or lung trouble? Did the breast-fed infant eventually reach adult life in a more healthy condition than an infant who had been bottle-fed? Were not many failures attributed to patent foods due, in the main, to the fact that these foods were not suitably modified? Did the boiling and sterilizing of raw milk make it a really suitable food for infants? Turning to the question of sleep Dr. Owen asked whether the nervous tired child was a product of recent times or had it always existed in one form or another? What advice was commonly given to a parent who complained that her baby would not sleep? As to rickets he did not believe that the last word had been said. Could it be guaranteed that a child would never show signs of the disease even when it had been brought up in the most modern conditions which aimed at prevention? Finally what part did the clothing play in the development of the infant?

Professor H. A. HARRIS showed a series of lantern slides illustrating the growth laws of the bony nervous lymphoid genital and other systems. He considered that it was a mistake to speak of any particular build of the body as essential to health. Almost any build was compatible with a healthy life. The foundations of teeth structure were determined long before the proportion of vitamins in the food could have any effect and a well-fed mother probably accounted for much more in the dental well-being of her offspring than the child's absorption of vitamin D. Dr. VAUGHAN PENDRED strongly advocated cow's milk undiluted with water as a diet for the young child. Another rule which ought to be observed was to insist upon a period of sleep or repose after feeding. Dr. BERNARD MYERS said that the ideal food for the infant was human milk; in the absence of that he would continue to use a certain mixture of milk and water and carbohydrates. He had even found full cream condensed milk useful at times. Dr. JAMES FENTON (M.O.H. Kensington) said that during the past ten or twelve years London milk had been pasteurized. Had surgeons noticed during that period a positive decline in gland and joint tuberculosis? Dr. A. M. COOKE on the subject of pasteurized milk said that he had recently seen a man of 55 suffering from gross scurvy; the man had been living on shredded wheat and on the milk supplied by a well-known London dairy. The condition cleared up after the administration of vitamin D.

Dr. ROLAND CURTIS said that clinicians often did not understand the technique of breast-feeding. Many children were put off the breast because they were said to have constipation which on examination was found not to exist at all. We had not yet got clean milk in this country, and this would not come about until pasteurization was compulsory. Pasteurized milk was excellent if the process was properly carried out. Dr. J. F. HALLS DALLY said that pasteurization in big cities was more or less a necessity, though a pasteurized milk did not necessarily mean a clean milk. Dr. KINGSTON BERTON agreed with other speakers in emphasizing the importance of cow's milk provided it could be obtained pure, and he believed that Grade A was in any case better than pasteurized milk in this respect. In his early practice he invariably found that the children who had perfect teeth had been breast-fed. The next best teeth were seen in children who had had cow's milk, while defective teeth occurred in children fed on patent foods. Dr. GERALD SLOT commented upon the amount of sleep lost by young children in working-class homes owing to conditions of overcrowding and to the disturbance caused by the wireless. Dr. MARCUS touched on some psychological problems affecting the child's welfare, such as those resulting from the arrival of a new baby. Dr. MARGARET LOVEWELD found some psychological difference between breast-fed and bottle-fed children. The latter seemed more predisposed to psychological trauma. Dr. WHITCHURCH HOWELL, speaking as an orthopaedic surgeon, said that rickets and deformities were still very much in evidence, and pleaded for more team work in the elucidation of the rickets problem.

Dr. H. H. MILLS, in summing up the discussion, drew attention to the way in which clinicians could help the nursing mother who was beginning to be fatigued by nursing the child feeding at four-hour intervals instead of at shorter periods, and when breast feeding was beginning to fail by supplementing with cow's milk and other foods.

INTRA-THORACIC NEW GROWTHS

At the December meeting of the Liverpool Medical Institution, with the president, Professor W. BLAIR BELL, in the chair, Dr. LESLIE CUNNINGHAM read a paper on Intra-thoracic new growths.

He said that the majority of cases of intra-thoracic tumours were carcinomata arising in the bronchi. One case of sarcoma and a series of seven primary growths which he regarded more mainly as cell carcinomata. These were subdivided into cases with (1) evidence of pleural effusion, (2) early haemoptysis, (3) evidence of localized pressure on the lung, and (4) a variety of symptoms in which the diagnosis was not obvious on examination. Pain was a frequent feature, and the majority of the cases with pleural effusion showed evidence of pleural pachymeningitis. Bronchoscopic or mediastinal confirmation was sought in all cases, and considered an increasing sign. Dr. CUNNINGHAM showed radiograms illustrating various cases, particularly with reference to the differential diagnosis. One case [illegible] a sarcoma. Other cases showed [illegible] lung, a large pressure [illegible] cases of pleural effusion. In these [illegible] were [illegible]. Other [illegible] effusion [illegible] large [illegible]

The [illegible] growth was [illegible] common [illegible] a [illegible] of [illegible] The [illegible] was [illegible] C. [illegible]

disease in the lungs were sufficient to define so as to call for a diagnosis at a tolerably early stage. Dulness with silence and paralysis of the left recurrent laryngeal nerve were signs which, even in the absence of other physical phenomena, should be regarded with the gravest suspicion.

In the discussion that followed the PRESIDENT said that lead therapy had been withheld in such cases owing to the belief that massive recrosis might occur. Only few had been so treated. He recalled, however, at least one case in which life had been greatly prolonged. He thought that with the better preparations and methods now employed it would be worth while considering the possibilities of lead therapy again, for there seemed otherwise to be no hope for these patients.

Mr. JOHN T. MORRISON urged that there was great need for still earlier diagnosis. Even in the case of tumours acknowledged to be malignant he pleaded for a more optimistic outlook. Radium treatment was still in its infancy; actual resection of such tumours was known to have resulted in cure in a few reported cases, and in certain cases of supposed unresolved pneumonia surgery alone could elucidate the diagnosis. For these reasons still earlier recourse should be had to the roentgenologist and the surgeon should be called in to complete the team. Dr. CHATTERLAIN spoke of the difficulty in the diagnosis of pulmonary neoplasms from inflammatory lesions, especially low grade types of pneumonia with purulent infiltration. Dr. T. B. DAVIE referred to the histological basis of the types of bronchial carcinoma described and stressed the fact that all these types were often represented in the same tumour. In most cases of oat-cell carcinoma, if sufficient blocks were cut from different parts of the tumour, some sections would reveal the presence of epithelioma with typical cell nests.

In a discussion arising from a note read by Dr. S. B. HEPD on two cases of attempted abortion the PRESIDENT called attention to the condition of pseudo-pregnancy. There was generally the fear of pregnancy with amenorrhoea. In these cases the corpus luteum of the preceding menstruation was persistent and large. Attempted abortion in such circumstances had come within Professor Blair Bell's own experience, and the absence of pregnancy altered the medico-legal aspects of the case. He agreed that it was difficult always to believe that a woman, especially when nulliparous, could herself pass an instrument through the os uteri. He generally suspected that she was shielding someone else by her statement. He considered that all cases in which the practitioner was in doubt as to the correct course to pursue he should report the matter to the medical officer of health and throw the responsibility of action on him.

Dr. GLYNN WHITTLE read a paper on the prevention of cancer.

TRANSPLANTATION OF FIBULA

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. F. GILL read notes on a case of transplantation of the fibula.

[illegible] 10 [illegible] 27 [illegible] of [illegible] of [illegible] An [illegible] On [illegible] On [illegible] of [illegible] of [illegible] small [illegible]

abscess cavity in the lower portion These cavities were opened cleaned out and packed and when they had healed the child was discharged from hospital with a request to return in six months

On readmission in August 1929 the upper part of the fibula was grafted into the upper part of the tibia A series of skiagrams showed the fibula in good position with new bone formation and increase in thickness

A walking caliper splint was fitted and the patient was discharged from hospital with a request to return in four months Unfortunately she did not return until May 1931 when she had outgrown the caliper and was walking with a marked varus deformity The only method of dealing with the present condition was to transplant the lower end of the fibula into the lower end of the tibia after the varus deformity had been corrected A series of skiagrams since then showed the lower end of the fibula in good position and bony union had taken place The fibula as a whole showed marked hypertrophy and its lower end was beginning to thicken At the end of November the leg showed two inches of shortening genu recurvatum was still present but the patient could walk well and the functional result would be very satisfactory

In his commentary Mr GILL said that several similar cases had been reported In 1906 Goldman of Freiburg reported a case of grafting of the upper end of the fibula after removal of the upper part of the tibia for sarcoma Stone in 1907 reported a case where there was a loss of eight inches of tibia He performed the operation in two stages the first was similar to that described the second consisted in splitting the lower end of the fibula and grafting the inner fragment to the lower part of the tibia Mr R A Stoney had reported a case in which the upper part of the tibial shaft was completely destroyed and a grafting of the upper part of the fibula was done, with excellent results

The PRESIDENT said that in his case there was not nearly such an extensive loss of bone It was extraordinary to watch the development of the fibula as time went on Mr W DOOLIN mentioned two cases of acute osteomyelitis on which he had recently operated and condemned the procedure of primary diaphysectomy Mr H STOKES said that if the tibia was taken out in a case of acute osteomyelitis non union always resulted He regarded diaphysectomy as quite unjustifiable Mr H F MACAULEY thought that a primary diaphysectomy should only be done when x rays showed periosteal involvement of the bone

Mixed Parotid Tumour

Mr J C MCMULLIN read notes on a case of mixed parotid tumour The outstanding features were (1) the marked slowness of growth (2) the pre operative facial paralysis (3) the repeated recurrence without metastases or glandular involvement

The patient was a woman 48 years of age who had contracted mumps in 1895 A small lump persisted in the parotid region which was removed three years later but recurred immediately It was again removed in 1901 but again recurred until in 1913 it gave rise to facial paralysis dysphagia dyspnoea and some pain for which surgical intervention was again sought It was not then thought possible to deal with the tumour successfully and it continued to increase in size until in 1924 it had become as large as a melon extending from the zygoma to the angle of the mouth over the lower border of the mandible pushing the ear upwards and backwards spreading deeply into the neck and enveloping the ascending ramus and temporo maxillary joint There were neither metastases nor glandular involvement Complete extirpation of the whole gland was done in December 1924 In the six years which have since elapsed there had been no recurrence

The PRESIDENT said that it was quite impossible to remove tumours such as this without the occurrence of facial paralysis He had a somewhat similar case at present and felt encouraged to operate when he saw Mr McMullin s good result

Reviews

GREAT DOCTORS

Professor HENRY E SIGERIST is proving himself a worthy successor to Dr Sudhof in the chair of the history of medicine at Leipzig In his present volume[1] he covers much ground in 292 octavo pages Beginning with Imhotep, who is claimed as an architect of the Great Pyramid he ends with Lister and Max Pettenkofer His plan has been to select the names of prominent writers at different periods of the world's history give a short but clear account of the place they held in contemporary knowledge and write a little biography of each introducing some characteristic anecdote or pregnant saying Thus of Galen s mother he reports that she was so passionate that she bit her maids and was so quarrelsome that her husband led a worse life with her than Socrates did with Xantippe Billroth he tells us used to say that a surgeon should only operate when there was some chance of success otherwise the noble art of surgery was prostituted and brought under suspicion both of the laity and of colleagues—a very true observation when brilliant surgery was the rule rather than the exception in the great teaching centres of Europe Wherever it has been possible Professor Sigerist has added a portrait and in the choice of these he has gone to original sources Many of the illustrations therefore, are new and he is to be congratulated upon the results They must have taken much time and labour to discover and they are admirably reproduced It is evident that Professor Sigerist has read widely He quotes in nearly every instance from the author himself and he adds a short and fairly complete set of references for those who wish to know more

It is remarkable as one reads how school of thought succeeded school of thought throughout the ages A great teacher would arise, sometimes remarkable for his personality sometimes for his ability as an experimenter sometimes merely for his power of expressing thoughts in words without any reference to facts—a mere theorist The pupils and imitators of each had their little day and after a few years or a few generations were replaced by those of another school The followers of Hippocrates and the Asclepiads were replaced by the Galenists and Paracelsus Harvey s work was continued and enlarged by Malpighi Santorio Van Helmont and Sylvius the immense personality of Boerhaave inspired Van Swieten de Haen and Haller Sydenham brought the student to the bedside , and Lister s work is still bearing good fruit in every part of the world

Professor Sigerist points out what different branches of medical science have dominated different centuries In the sixteenth century Harvey was experimenting and physiology was dominant being greatly aided by the introduction of the microscope in its later years In the eighteenth century the greater minds were concerned with pathology, and in England Hunter was the outstanding example During the nineteenth century theoretical medicine was falling into disrepute and clinical medicine was beginning to take its place The twentieth century is developing therapy on entirely new lines Medicine has always and necessarily, been dependent upon science for its progress Anatomy botany physics and chemistry have in turn aided We are rather inclined to underestimate the difficulties of earlier experimenters until we are told that Santorio when he counted the pulse had to make his own pulsilogium for the watches of the time had no second hand and no minute hand His

clinical thermometer was a glass ball which the patient held in his mouth connected by a graduated tube with an open mass of water.

There is still much we should like to know and there are questions that Professor Singer has left unanswered. How for instance did Vesalius write the seven books of the Fabrica by the time he was 27 and what did he mean by that pilgrimage to Jerusalem which ended so fatally for him. But perhaps it is fine asking with Sir Thomas Browne what song the Sirens sang. Professor Singer has produced a good book. He has chosen well and has not limited himself to any one age or country.

D'ARCY POWER

DIABETES MELLITUS

In his lecture *The Pathology of Diabetes Mellitus* Dr. SHIELDS WARREN has made use not only of material obtained from the post-mortem room but also of tissues removed surgically. The basis of his work rests on 300 autopsied cases definitely diagnosed as diabetes mellitus. Dr. Warren has produced a complete and exact histological account of the conditions found in this disease beginning with the pancreas itself and continuing with a short and beautifully illustrated chapter on the abnormal distribution of glycogen in the various organs and tissues. The histological evidence of abnormal deposition of lipoid material in the spleen and reticulo-endothelial system is discussed together with other signs of abnormal fat metabolism. The author makes an interesting digression on the relation of gall bladder disease to diabetes. He concludes that the well-known association of gall stones with diabetes is best explained by considering the stone as a result of disturbed lipoid metabolism dependent on the diabetes. Nevertheless he advocates cholecystectomy for all diabetic patients with evidence of gall-bladder disease. His views on coma are dogmatic and we believe worthy of attention. If by this is meant diabetic coma developing in a well-treated diabetic it practically always means infection. In a patient with diabetic coma dying in spite of treatment it is usually difficult for the pathologist to say which changes noted from the pathological-physiological changes that characterize coma. [illegible] coma by chemical determinations of carbon dioxide combining power of the blood. Of Dr. Warren's own experiments into the [illegible] he discusses the [illegible] of arteriosclerosis in the diabetic. He does not regard the high blood cholesterol [illegible] as a cause. Lipoids are not the first cause of arteriosclerosis. The greater incidence of coronary thrombosis [illegible] in the diabetic. The normal urine is not affected by [illegible]. High blood sugar content [illegible] in the normal ground substance [illegible] to the vessel wall [illegible] to the presence of lipoid material [illegible] to arteriosclerosis. A SYSTEM OF BACTERIOLOGY

Volume IX which completes this *System of Bacteriology* is devoted to technique. There is a bewildering choice of methods available for the practical bacteriologist and as the editors of this volume point out two courses are open to the compilers of a treatise on this subject. Either everything can be included or one method only of established repute can be described for the carrying out of any single operation. The latter policy has been adopted and we think the choice a wise one. And since the choice of a method is so often a matter of personal taste we feel that a reviewer would be well advised to follow the lead given by the editors and refrain from any attempt to adjudicate between the methods described in this volume and those omitted. The broad lines on which the book is planned and the field that it covers should be his principal concern.

The opening chapter is devoted to laboratory design and is confined to a description of two of the most up-to-date buildings in the country—the Sir William Dunn School of Pathology, Oxford, and the Department of Pathology, Cambridge. Plans and photographs [illegible] are given of the several departments. Following this we have chapters devoted to the microscope and demonstration of bacteria, the preparation of culture media, the determination of [illegible], the cultivation of [illegible] anaerobes, isolation from single cells and so on. A whole section is devoted to [illegible]. The chapter on [illegible] occupies [illegible] pages and [illegible] pages are given to [illegible]. We have here a wealth of information on [illegible] and many chapters of [illegible] from [illegible] of the various [illegible] with [illegible] commonly [illegible] will be found [illegible]

[illegible]

bacteriologists in the future, and might well be dealt with in subsequent editions

Undoubtedly some experienced workers will criticize this volume because they do not find described the methods to which they have given their affections and perhaps a great deal of their technical ingenuity, preference for a method is held almost as strongly as a religious belief! But the uninitiated desirous of knowing how to set about any piece of practical work in medical bacteriology will find what he wants clearly described The volume concludes with a general index for the whole *System* Some no doubt who only wish to purchase single volumes will deplore the fact that each volume has not a separate index and it is certainly a drawback The policy of having one general index and no more might possibly be reconsidered when new editions of the *System* become necessary

BOOKS ON PSYCHOPATHOLOGY

We have received two pamphlets which are published under the auspices of the Medical Society of Individual Psychology The editor Dr F G CROOKSHANK states that one objective held in view by this society—besides its primary intent to study and pursue the teachings of Alfred Adler—is the better acquaintance of the practitioner with the fruits of modern psychology and their applicability in the field of general medicine The hope is expressed that the appearance of a series of publications on individual psychology will go some way towards the furtherance of this aim The first pamphlet *The Case of Mrs A (the Diagnosis of a Life Style)* [5] gives some idea of the Adlerian method of interpretation in a concrete case of neurosis for it records the comments made by Dr Adler on the notes of a case presented to him for extempore consideration and impromptu interpretation This pamphlet will probably be most appreciated by those who are already familiar with Adlerian theory and practice and the second pamphlet which records a discussion on *Anorexia Nervosa* [6] is perhaps of more interest to the medical practitioner and general physician The discussion was opened by Dr Langdon Brown and thoroughly repays careful study for this disorder is by no means infrequent and there is every reason why it should be recognized in its early stages and the psychological factors involved in its development appreciated It is proposed to issue these pamphlets at least quarterly

Included in one volume is the translation into English of *Suggestion Therapy* by Dr Ernst Jolowicz and *Hypnosis and Hypnotherapy* [7] by Dr Gustav Heyer The analytical methods of treatment are now in the foreground and relatively little is heard of the methods with which the writers of this volume are concerned It would seem however that both suggestion and hypnosis have their value either alone or in combination with other methods Dr Jolowicz observes indeed that suggestive factors are involved in every form of psychotherapy though he does not hold the view that suggestion alone accounts for the successes in analytic methods of treatment This is an eminently practical book the technique of the psychotherapeutic methods advocated is given in detail and the authors maintain throughout a close touch with clinical realities The book is written with restraint is thoroughly readable and may be recommended as a useful introduction to the methods of treatment with which it is concerned

The Concentric Method in the Diagnosis of Psychoneurotics [8] is a translation of a series of lectures delivered by Dr M Laignel Lavastine Professor in the Faculty of Medicine of Paris The author's aim is to show the necessity in every case of psychoneurosis to apply what he terms 'diagnosis in depth' and not merely to be content with a superficial diagnosis The concentric method is carried out in its entirety in the diagnosis of psychoneurotics when the following five zones have been distinguished and as far as possible investigated first there is the peripheral psychic atmosphere then beneath this the nervous zone thirdly the endocrine zone then the visceral zone and lastly and innermost the central morbific kernel This is clearly a systematic method for investigating the individual as a whole in every case of neurosis and the informal and lucid lectures included in this volume admirably serve to demonstrate the writer's method of approach to his clinical material This book emphasizes the physiological aspects of the psychoneuroses which are liable to be overlooked or altogether neglected and it will certainly be read with advantage by those who are concerned with the treatment of psychoneurotic patients

INTERPRETATION OF DIAGNOSTIC AIDS

Laboratory investigations as aids to diagnosis and treatment make an ever advancing claim on the attention of the clinician and although experience teaches that here, as elsewhere the absolute proposition does not always stand secure no one nowadays questions the value of the contributions that can be made to practical medicine by the chemical bacteriological or x ray expert Naturally to be fully effective what is written in the laboratory must take its place beside the clinical facts and in addition must be intelligently interpreted when it reaches this position In the second volume of *Clinical Interpretation of Aids to Diagnosis* [9] the attempt is continued to secure this intelligent interpretation and we may say at once that the success of the first volume is here repeated If the complaint is sometimes made that experts are developing a special and technical vocabulary this is almost inevitable in a progressive art and it is clearly the clinician's interest or even his duty, to appreciate the findings which his laboratory colleague records This is one of the ambitions cultivated by the *Lancet's* volumes and the several contributors have set themselves to forward it Further advantages are to be found in indications of the circumstances in which laboratory tests may be useful in the kind of information they may give in their limitations and in the conditions to be observed in order to secure their maximum values When these general considerations are applied to sections—each written by an expert—dealing with such subjects as the diagnosis of acute food poisoning the microscopical examination of the faeces and of dermatological lesions bacterial blood cultures electrical reactions and dental and visceral skiagrams the range of service of the volume becomes evident Possibly here and there a practitioner may be stimulated to develop in some degree and fashion his own laboratory resources and thus the book excellent in itself may be also the cause of excellence in others In

psychologists in the future and might well be dealt with in subsequent volumes.

Undoubtedly some experienced readers will consult this volume because they do not care to describe the methods to which they have given their attention and perhaps a great deal of their technical ingenuity for more than a minute as dull almost as strong as a religious book. But the principal desire of knowing how to set about any piece of practical work in medical psychology will find what he wants clearly described. The volume concludes with a general index for the whole Series. Some one doubtless will be found to purchase single volumes will deplore the fact that each volume has not a separate index and it is certainly a drawback. The merit of having one general index and no more must possibly be reconsidered when new editions of the Series become necessary.

BOOKS ON PSYCHOPATHOLOGY

We have received two pamphlets which are published under the auspices of the Medical Society of Individual Psychology. The editor Dr. F. G. Crookshank states that one objective held in view by this society is "to assist all practitioners to study and pursue the methods of Alfred Adler—to the better acquaintance of the practitioner with the study of modern psychology and their application in the field of general medicine." The hope is expressed that the appearance of a series of pamphlets on individual psychology will go some way towards the attainment of this aim. The first pamphlet, *The Case of [illegible]*, is a [illegible] on the Adlerian method of interpretation in a concrete case of neurosis. It records the comments made by Dr. Adler on the notes of a case presented to him for examination, consultation and improvised interpretation. The pamphlet will be read with interest by those who are already familiar with Adlerian theory and practice, and the second pamphlet, which records a discussion of Adler's [illegible] of more interest to the medical practitioner and general reader. The case discussed was reported by Dr. Langdon Brown and contains many useful suggestions. In this discussion the question of the relation of the psychological factors to the organic stages and the psychological factors involved in the development appeared. It is proposed to issue these pamphlets at least quarterly.

Included in the volume is the translation into English of *Spirits* by Dr. Ernst Jahrreiss, and *Hysteria* by Dr. Gustav Hertz. The articles on methods of treatment are next in the sequence and relate more to the methods with which the writers of this volume are concerned. It would seem however that these suggestions and criticisms have their value rather as [illegible] with other methods. Dr. Jahrreiss observes, indeed that suggestive factors are present in every form of psychotherapy though he does not find the word that suggestion alone accounts for the successes in whatever methods of treatment. This is an important point for the exchange of the psychotherapeutic methods advocated is given in detail and the authors maintain throughout a close touch with clinical practice. The [illegible] is worthy of serious study as is the [illegible] by Dr. Hertz. The latter is more theoretical and may be found useful by those who are interested in the [illegible] of the [illegible] of the neuroses.

[illegible] by Dr. M. Layton-Bennett. The [illegible] Methods. The author's aim is [illegible] a [illegible] of practical methods [illegible] in the [illegible] of the [illegible] and [illegible] contact with a [illegible]. The [illegible] methods [illegible] and [illegible] of [illegible] practice. Readers [illegible] have [illegible] [illegible] the [illegible] [illegible] the [illegible] [illegible] the [illegible] [illegible] and [illegible] [illegible] [illegible]

any event it is certain that the contributors to the *Lancet* series have well applied themselves to the task of bringing into a mutually helpful partnership the clinician and the laboratory expert and their articles in not a few instances show that they themselves by no means dwell in remote academic seclusion but that on the contrary the individual problems of practical medicine have come within the range of their personal experience

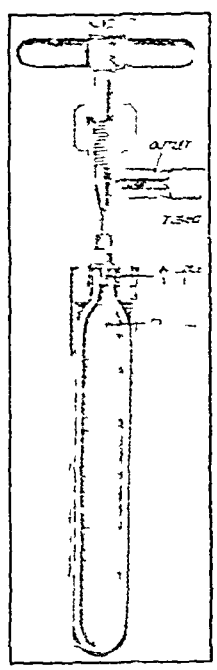
NOTES ON BOOKS

Three years ago under the presidency of Dr T H Jacob who had previously been in the chair in 1911 the Nottingham Medico Chirurgical Society celebrated its centenary and now has brought out a generously illustrated account[1] of its past and of some of the famous medical men of Nottingham such as Marshall Hall and Francis Sibson who afterwards became prominent in medical London Alexander Manson who in 1821 was a pioneer in the treatment of goitre by iodine apparently without any knowledge that this success had been published in the previous year by Coindet in France and W H Ransom who in 1845 by beating T H Huxley in the first M B London led as the latter stated to his entering the Royal Navy and so taking up science as his life's work Of the provincial medical societies the Nottingham Medico-Chirurgical Society is among the seniors coming after those of Warrington (1770) Colchester (1774) Gloucestershire (1788)—known as the Fleece Medical Society as it met at the Fleece Inn at Rodborough and famous for the papers Edward Jenner and Caleb Hillier Parry read there—Plymouth (1794) Leicester (1800) Halifax and District (1822) and St Helens (1826)

A genial idea of the energetic chief of the laboratory of pathological anatomy of the Pasteur Institute Professor A Peyron led to a systematic survey by Dr E Benech of the recorded association of parasites and cancers[11] The intimate etiological relation of nematode infestation with cancer of the stomach in the rat discovered by the genius of Fibiger gave a new significance to the sporadic occurrence of new growths in man and animals harbouring gross parasites Dr Benech's work is no mere enumeration of references to cases of this kind With carefully documented records of the association between neoplasms and the protozoan and higher forms of parasites he has considered their causal significance (if any) in the light of pathological and anatomical investigation of the material The original figures are reproduced from the majority of the better studied examples and in addition many new figures are included from material investigated by Dr Benech himself and from Professor Peyron's collection

Professor Peter Rona's Textbook of Practical Physiological Chemistry[12] has won the popularity it deserves and the second edition of the first part of it which deals with enzymes will be welcomed The various methods of preparation and isolation of the body ferments have been brought up to date and the latest suggestions in regard to laboratory technique have been incorporated Professor Rona approaches the subject from an unusual standpoint and the new edition of his book is a definite contribution to physiological chemistry

Egypt The Home of the Occult Sciences[13] by Dr T Gerald Garry is a short treatise on Imhotep whom Osler describes as "the first figure of a physician to stand out clearly from the mists of antiquity" The validity of this claim is examined by the author who gives some interesting information about the magical ceremonies and medical practice of ancient Egypt



The Health Organization of the League of Nations has recently issued three reports the respective official numbers being C H 957 961 and 1045 The first of these is a review of *Tuberculosis in Denmark Norway and Sweden*[14] by Drs Ostenfeld Heitmann and Neander The authors discuss particularly the mortality from this disease in the three Scandinavian countries and the progress effected in the organization of anti tuberculosis activities Professor Knud Faber the author of the second report describes the existing *Medical Schools in China*[15] with special reference to their administration degrees of efficiency and interrelation The third volume is a report of the Preparatory Committee of the *European Conference on Rural Hygiene*[16] and relates to the principles governing the organization of medical assistance the public health services and sanitation in rural districts

PREPARATIONS AND APPLIANCES

Portable CO Apparatus

A simple effective and convenient adjunct to the practitioner's midwifery and anæsthetic bag is the portable apparatus for the therapeutic administration of CO manufactured by Sparklets Ltd (Upper Edmonton N 18) and illustrated herewith It consists of a metal holder carrying a six inch cylinder of gas The valve apparatus is screwed down into the holder the mouth of the gas cylinder being pierced in the process by a needle The flow of gas thus released is controlled by the fine adjustment valve key at one end of the apparatus and delivered through a rubber tube leading off from the outflow pipe The tube can be attached underneath an ordinary Schimmelbusch mask placed in the patient's mouth connected to a glass funnel or to a rubber catheter inserted into the naso pharynx The valve key gives a delicately regulated stream of gas but if need be a small rubber bladder can be incorporated in the delivery tube so as to ensure an even flow Each cylinder produces about 12 litres of the gas and at the maximum rate of flow will last for at least six minutes Refill cylinders of which six are supplied can be inserted easily and with loss of very little time The apparatus is neither cumbersome nor heavy being only ten inches long and weighing a trifle over 1¼ lb As a readily available source of respiratory stimulant this CO_2 resuscitator is to be recommended

Uterine Cannula

Mr H J Drew Smythe M S F R C S (Clifton) writes The instrument shown in the accompanying figure was devised to render the intrauterine injection of glycerin a simple procedure without disturbing the patient too much It has the advantage over other instruments of like nature in that it is rigid and can be inserted by feeling for the open os

of the cervix with the cannula itself and there is no necessity for inserting a guiding finger or in the majority of cases even a speculum After inserting the cannula a Record or other syringe is fitted to the end containing two ounces of glycerin which is slowly injected into the uterus This cannula was made for me by Messrs Thackray of Leeds and later by Messrs Down Bros of London The instrument can be obtained from either firm

The Health Organization of the League of Nations has recently issued three reports the respective official numbers being C H 957 961 and 1045 The first of these is a review of *Tuberculosis in Denmark Norway and Sweden* by Drs Ostenfeld Heitmann and Neander The authors discuss particularly the mortality from this disease in the three Scandinavian countries and the progress effected in the organization of anti-tuberculosis activities Professor Knud Faber the author of the second report describes the existing *Medical Schools in China*[13] with special reference to their administration degrees of efficiency and interrelation The third volume is a report of the Preparatory Committee of the *European Conference on Rural Hygiene*[14] and relates to the principles governing the organization of medical assistance the public health services and sanitation in rural districts

PREPARATIONS AND APPLIANCES

Portable CO Apparatus

A simple effective and convenient adjunct to the practitioner's midwifery and anæsthetic bag is the portable apparatus for the therapeutic administration of CO manufactured by Sparklets Ltd (Upper Edmonton N 18) and illustrated herewith It consists of a metal holder carrying a specimen cylinder of gas The valve apparatus is screwed down into the holder the mouth of the gas cylinder being pierced in the process by a needle The flow of gas thus released is controlled by the fine adjustment valve key at one end of the apparatus and delivered through a rubber tube leading off from the outflow pipe The tube can be attached underneath an ordinary Schimmelbusch mask placed in the patient's mouth connected to a glass funnel or to a rubber catheter inserted into the nasopharynx The valve key gives a delicately regulated stream of gas but if need be a small rubber bladder can be incorporated in the delivery tube so as to ensure an even flow Each cylinder produces about 12 litres of the gas and at the maximum rate of flow will last for at least six minutes Refill cylinders of which six are supplied can be inserted easily and with loss of very little time The apparatus is neither cumbersome nor heavy being only ten inches long and weighing a little over 1½ lb As a readily available source of respirator stimulant this CO resuscitator is to be recommended

Aluminium Cannula

Mr H J Dear's Mark VI F R C S Cannula The instrument shown in the accompanying figure has been devised to remove the temptation of giving a simple procedure a bad name by its too frequent performance It has the advantage over other instruments of this nature in that it is rigid and can be inserted by feeling for the opening

THE FUNCTION OF THE COLON

While the completion of digestion and the absorption of the digestive products are some of the duties of the colon its principal function in the proximal part is the absorption of water The comparatively fluid chyme from the small intestine is dried in the colon leaving only a pultaceous or firm mass by the time the sigmoid and rectum are reached It is, however, in the excretion of waste products from the digestive tract, and their expulsion in defaecation, that the lower part of the colon finds its essential function The movements of the colon are apparently different from those of the small intestine Both the small and the large intestine show segmentation or pendulum movements, which bring fresh absorptive portions of mucous membrane into contact with the digesting contents of the bowel The peristaltic wave of the small intestine, characterized by a relaxation in front of a wave of contraction, is not so evident in the colon beyond the splenic flexure, though the proximal part of the colon tends to fill by the slow onward passage of material from the small intestine In addition, the colon shows a new form of movement in which a mass of contents is forced through a considerable length of the large bowel The longitudinal muscle of the colon appears to be mainly responsible for this mass movement and in order that it may occur in normal manner two conditions must be satisfied that the colon has been filled as far as the splenic flexure, and that having filled thus far the transverse colon is so relaxed that maximal filling of this part of the bowel takes place The mass movement then starting in the neighbourhood of the hepatic flexure, sweeps the contents of the transverse colon into the descending and sigmoid portions Defaecation may follow, or the ingesta may remain till the next mass movement propels them into the rectum This mass movement is often set up when fresh food enters the stomach and was described by Hurst as the result of a gastro colic reflex The details of the mass movement were observed by studying an opaque meal on the fluorescent *x*-ray screen and most of the observations on movements of the colon have been made by *x*-ray workers in the course of routine examination of patients suspected of gastro-intestinal disease It is probable that both the segmentation movements and the peristaltic waves are initiated in the nerve muscle mechanism of the wall of the bowel though external influences may exert control through the vagus and sympathetic nerves The chemical constitution and reaction of the bowel contents as well as the physical state as regards bulk and roughness form the adequate stimulus for starting the segmenting and peristaltic movements

Although the physiology of the colon is thus somewhat obscure a great deal of work has been done on the deranged colon Most of this is embodied in the experience of *x*-ray workers, appearing in their interpretation of radiograms obtained during routine examination of patients rather than in any treatise on the subject The Frankfort school has, however, endeavoured to classify the diseased function of the colon and a short summary of its work on the physiology and pathology of the movements of the colon has already appeared [1] It is rare to find a colon so flaccid and atonic that segmentation movements are entirely absent It is rather in the derangements of the "mass movement" that minor functional disorders of the colon occur The hurried movements of diarrhoea are less easily studied, and the largest advance in knowledge has taken place in the conditions underlying delay in the colon and constipation Several forms of disordered mass movement may occur (1) A complete absence of the normal mass movement so that the contents of the colon are slowly pushed on into the descending and sigmoid portions, giving rise to inspissation of the contents, delay of several days' duration and evacuation preceded or accompanied by colicky pain (2) Premature and insufficient mass movement may take place, before the transverse colon has been filled, the contents of the ascending colon remain therefore, *in situ* and delay of the ascending colon type is seen (3) In a condition of spasm of the colon, the mass movement may be unable to pass the spastic regions, in this way the contents are broken into pellets or cork-like portions, and evacuation is delayed (4) In elderly patients a mass movement may be delayed for thirty to thirty-six hours, owing to enfeeblement of the musculature of the bowel (5) It is possible too, that a primary form of constipation may follow too complete absorption of the ingesta, so that there is not sufficient stimulus to the nerve-muscle mechanism controlling the bowel movement

The purely anatomical position of the bowel can no longer be considered of importance nor can it be shown that disordered action of the colon is remedied by surgical procedures, involving stitching up and fixing dropped portions The living pathology of the bowel is much more concerned with its mobility, as expressed in its functional posture or tone, and its various types of muscular movement How the control takes place is not yet completely known, but it is dependent on the triad—bowel contents mucous membrane nerve-muscle mechanism Any one of these may be affected In a recent paper on functional disorders of the colon, Spriggs,[2] discussing the causation speaks of the importance of infections Toxic sources may be present in the bowel contents, as in dysentery, in the upper digestive tract, as in pyorrhoea and infected tonsils, or in adnexa of the alimentary tract, as maxillary antra, gall-bladder Bad food, food deprived of vitamins in its preparation, may have a deleterious effect Spriggs

[2] *Quart Journ Med* July 1931 p 533

lays more emphasis however on the harmful effect of irritative elements which interfere with the rhythm of the body's swing up and downs and spasms. Prolonged use of such items must upset the normal nervous mechanism regulating the postural tone and allowing dilatation and relaxation of the colon.

READING AND SEEING

Most of us are conscious of variations in the pleasantness and readability of print but impressions need to be corrected by measurements that can be confirmed. Many such experiments have been made and Mr. M. D. Vernon in *The Experimental Study of Reading*[1] gives an interesting account of attempts to obtain some workable data. Some of the experiments and the apparatus devised have been most ingenious and not least are the very elegant tests performed by Mr. Vernon himself. One of the difficulties encountered is the disturbance caused by any attachment of a piece of apparatus to the eye itself which restricts the movements of the eye. On the other hand light beams projected upon the eye are apt to disturb vision. How these difficulties have been overcome is clearly set out by Mr. Vernon in his treatise.

Voluntary and reflex movements about the field of vision are in general inaccurate and erratic. To pass from one part of the field to another it is usually necessary to execute corrective movements interspersed with fixation pauses during which the eye so to speak reviews its position. Nor can the eye be maintained steadily in one fixation position for any length of time; there is a tendency for it to move away as the result of reflex stimulation from peripheral visual sensations. The movements of the two eyes are not always well integrated and they may differ from each other both in speed and direction. In the reading of the child the fixation pauses and movements to and fro along the printed lines are erratic and very numerous. In the reading of the mature adult a series of rhythmic backward and forward movements may be observed, the forward movements alternating regularly with fixation pauses of comparatively short and regular duration. This harmonious sequence of movement and pause is liable to be disturbed by any kind of mental struggle or conflict such as an effort to understand an obscure passage or to pronounce some difficult word, like perspiration, or translating one mental function to the reading of visual symbols. In such cases periods of [illegible] with a return to the regular [illegible]. [illegible] and more than a small part of the visual field [illegible] the conduct of [illegible] and [illegible] language and [illegible]. In [illegible] [illegible] [illegible]

Himalayan peaks are to be climbed at all, the use of such an artificial aid as oxygen should be dispensed with lest the noble sport of climbing be reduced to a mere laboratory experiment Quite apart from considerations of this kind comes the problem of oxygen in relation to acclimatization One school thinks that oxygen is of use to the unacclimatized , another that it is valuable both for acclimatized and unacclimatized persons Practical experience seems unable to settle the matter The no-oxygen ' adherents quote the fact that in 1924 some members of the expedition had reached such a pitch of acclimatization that no enhanced fatigue was experienced when, climbing at 26 000 feet they turned off the taps of the oxygen apparatus Again Mallory s party reached a point 26 900 feet above sea-level without using oxygen, and relied entirely on their inherent powers of acclimatization On the other hand, Finch and Bruce encamped at a height of 25 500 feet found considerable relief from oxygen, which enabled them to throw off a ' dead numbing cold ' and ' sleep well and warmly " Finch was sure that the oxygen saved their lives that night Moreover, the next day its use enabled them to climb at 900 feet an hour while another party without oxygen, but in better mountaineering condition attained a climbing speed of only 330 feet an hour in almost similar conditions Thus Dr Raymond Greene suggests that the necessity for acclimatization might be avoided if oxygen were used from low levels upwards This would call for an apparatus which delivered the gas constantly day and night and the danger of its sudden failure at a high altitude would be considerable The difficulties in designing such an apparatus—which must be light, simple efficient and thoroughly trustworthy—are obvious Dr Greene believes however, that should it be finally obtainable and placed in the hands of a young, well-drilled and well-organized party a successful assault on Everest would result Acclimatization to high altitudes presents a difficult problem its most important element being as he points out, the alkalosis resulting from the washing out of CO_2 from the lungs during deep breathing It is interesting to note that experiments in administering ammonium chloride to combat this alkalosis have already been made, and open a promising field for investigation

GASTROPHOTOGRAPHY

In his manual on gastrophotography[1] Dr Becart describes fully the methods of using and the results obtained with an instrument for taking direct photographs of the lining membrane of the stomach Preliminary notices of the use of the instrument advocated, the gastrophotor have been published in England by Professor Pannett and Mr Levi,[2] and by Dr Wyard [3] The apparatus consists of two cylindrical metal cameras separated by an ampoule containing a tungsten filament by means of which a flash of cold blue light of 20 000 candle-power is obtained Each camera has, instead of lenses eight pinholes arranged in pairs vertically the pairs facing directions at right angles to each other The single exposure thus enables eight stereoscopic pictures to be obtained of the whole circumference of the stomach The double camera is mounted at the end of an oesophageal tube for introduction into the stomach, and the apparatus is so constructed that the holes are not uncovered until the cameras are in place The minute pictures of the interior thus obtained are developed and enlarged before examination Dr Bécart's monograph is divided into two sections a simple and clear description of the gastrophotor and the technique required in its use , and, secondly a discussion of the results obtained in normal patients and in those suffering from various types of gastritis ulceration, and tumours of the stomach It is illustrated by a series of photographs of actual lesions and diseases of the stomach, as well as by control pictures of the normal appearances of the different parts of the mucous membrane In this generation much progress has been made in elaborating diagnostic methods Radiology has especially increased the knowledge of the viscera, but only a few organs, such as the throat, larynx bladder and rectum, can be brought under direct vision In the case of the stomach the gastroscope is an instrument that requires special care, and its field of vision is limited Photography of the stomach wall by the gastrophotor offers a useful addition to our diagnostic methods Though at present in the trial stage, its use may well become more general, and Dr Becart has provided a good introduction for those who think of taking up the subject

MEDICAL CINEMATOGRAPHY

The December meeting of the Chelsea Clinical Society was given up to a demonstration of medical cinematograph films Four of the five films shown, which occupied two hours in projection were of surgical or orthopaedic interest the remaining film being a biological study Film technique for scientific illustration has advanced far since the first instructional efforts were made some years ago, but the difficulties of medical subjects are quite special An operation on a patient cannot be prolonged or altered in its routine to suit the exigencies of the cinematograph camera It is inevitable also at times that the surgeon's hands or instruments should interfere with a clear view, and the light though adequate for the manipulations may not be the best for photography On the other hand, the film has obvious advantages for the student as compared with witnessing the actual operation for it can be stopped at any point turned into a still picture, and its detail examined, or a particular phase of operation may be repeated as often as necessary The demonstration at Chelsea was given by Mr Lawrence Abel, who was himself responsible for one of the films shown, a two-reel production illustrating the abdominal perineal (Miles s) operation for radical excision of carcinoma of the rectum an operation designed to extirpate the upward spread of the growth in addition to the lateral and downward spread This was a very graphic presentation, carrying the whole procedure through from the first preparation of the patient to the post-operative dressings and of special interest was the technique for restoration of the pelvic floor and the making of the colostomy Mr Abel in a foreword to the series of pictures, remarked that in this country, so far as he was aware, there was as yet only one medical talkie " though the Western Electric Company was starting a library of talking medical films The single

sound film was an American production illustrating an obstetric procedure and took an hour to project. The five films he showed were all silent, most if not all of them from the Kodak Medical Film Library. Naturally surgical and orthopaedic subjects lend themselves better to moving picture technique than do strictly medical subjects. The consultation room as distinct from the operating theatre awaits the sound film and Mr. Abel appeared to think that some day when the making of talkies becomes less expensive teaching centres or groups of medical men may be able to establish a studio where medical subjects can be taken. In America medical and surgical films for the hospitals where they are made are subsidized to some extent by firms which sell dental devices, infants' foods and the like, and in return some advertisement of the preparation is insinuated though not obtrusively into the film. The first of the films shown by Mr. Abel illustrated the setting of fractures of both legs as carried out by Mr. Watson Jones of Liverpool, and this was followed by a view of Continental practice from the Accident Hospital, Vienna, where Professor Lorenz Böhler was shown at work treating fractures of the humerus and devising splints of unusual character. Professor Böhler's films were described in these columns on the occasion of the visit of the Austrian surgeon to this country last year. The next film showed an operation by Mr. Norman Fleming for the removal of cataract, followed by some close-ups of eyes on which such operations had been performed. Another film showed the removal of tonsils by dissection as practised by Mr. J. R. Griffith. These relatively simple operations at short range were very successfully illustrated. Finally came a film of biological interest, the work of Professor K. Kopsch of Berlin, illustrating the development of the fertilized ovum of the axolotl. By arranging exposures at fixed intervals the picture was made to represent in a few minutes various stages of growth which actually occupied hours or days, so that the life-history of the subject was presented in a very vivid manner.

MENTAL MEDICINE YESTERDAY AND TO-MORROW.

In a note on Sir Humphry Rolleston's reminiscences of St. George's Hospital forty years ago[1] we suggested that it would be a good thing if other senior members of the profession put down on paper their recollections of bygone physicians and surgeons. A correspondent reminds us that just twelve months ago[2] Dr. Lionel Weatherly, who celebrates his eightieth birthday next month, published a short address on some leaders in psychological medicine with whom he had been associated during half a century of work among mental and nervous patients. Beginning with Sir John Bucknill (author with Daniel Hack Tuke of a textbook famous in its day) he mentioned in turn Rayner, David, Bower, Henry Maudsley (whose writings he devoured), the three great Scotsmen—Clouston, Yellowlees and Urquhart, Savage, Hayes Newington, Conolly Norman and Frederick Needham. Sir Clifford Allbutt (who as some of us forget was Commissioner in Lunacy for a time), Hood, Micklethwaite, Whitcombe and Spence and last but by no means least Charles Mercier, of whom Dr. Weatherly said: "Next to Maudsley I place him as our most brilliant writer on anything appertaining to mental diseases." Mercier's pungent pen was very familiar to readers of the *British Medical Journal* up to the time of his death in 1919. Turning from giants of the past to hopes and wishes for the future, Dr. Weatherly summed these up as follows: "I do wish for more enlightenment regarding the influence of endocrine secretions on mental disease. I desire more knowledge of the sympathetic nervous system and its power over emotional states and impulses in functional conditions of insanity. I want more clinical study in our mental hospitals, better classification of our patients, greater use made of psychotherapy, it by that is meant gaining the confidence of our patients and persuasion by logical reasoning to remedy morbid imaginings; and lastly, I look forward to a great extension of occupation therapy in the treatment of mental disease."

ARTHUR CONAN DOYLE.

The Rev. Dr. John Lamond's memoir of Sir Arthur Conan Doyle[3] who was a many-sided personality shows how much the biographer's view of his subject determines the presentation of the aspects of his subject and even suggests that in this and in some similar instances a really satisfactory account would be more likely to result from a combined authorship. To most people Conan Doyle was the creator of Sherlock Holmes and first and foremost a man of letters; to medical readers he has the additional attraction that he was a member of their profession and in some of his stories brought his special knowledge to bear with accuracy and dramatic effect. His activities included sport, oratory, politics, work as a war correspondent, history, poetry and spiritualism. It is the last aspect that seems to appeal most to his biographer and probably least to most of those who in the ordinary course would read this book. The volume is divided into two parts, the second and larger being mainly devoted to his spiritualistic propaganda. Conan Doyle came of an artistic family which numbered among its members Richard, familiarly known as Dicky, Doyle who designed the front cover of *Punch* and Conan Doyle might well have been an artist in colour instead of one in words. Born in 1859 in Edinburgh he was educated at Stonyhurst and began medicine in 1875 at the university in his native town, which the author naïvely remarks even at that period had a world-wide reputation as a centre of medical training. It will be remembered that Edinburgh always famous then had Lister at his zenith as a teacher. Conan Doyle came under the influence of Joseph Bell, the surgeon whom he immortalized as the prototype of Sherlock Holmes, and William Rutherford, professor of physiology, who was the model from whom Professor Challenger in *The Lost World* and later the provocative critic in *The Land of Mist* were drawn. Who was the original of Dr. Watson if indeed there was one is not revealed. In her pathetic epilogue Lady Doyle gives an interesting account of how when a man disappeared and the police failed to discover where he was the relatives appealed to Sir Arthur, who thereupon solved the mystery without leaving his study by indicating one or two towns hundreds of miles from the city in which

the murder was supposed to have been committed Dr Lamond gives a graphic account of Conan Doyle's struggle with poverty for six years in medical practice at Southsea then follows him to Devonshire Place London where there was a brief interlude as a patientless ophthalmic surgeon and so to success as an author Conan Doyle took an active part in the South African war and the great war and later gave his energies to spiritualism in which he had become interested as far back as the eighties of last century

CENTENARY MEETING PRESIDENTS OF SECTIONS

The scientific and clinical work of the Centenary Meeting of the British Medical Association to be held in London next summer under the presidency of Lord Dawson of Penn, P R C P will be divided among twenty-four Sections meeting on Wednesday Thursday and Friday, July 27th 28th, and 29th We publish below a list of the Sections whose Presidents have been appointed The first six Sections will meet each on three days and the last three on one day, the remainder will meet on two days The full list of officers and Sections and further information about the meeting generally will appear in later issues

OLD MEDICAL BOOKS

In a recent issue (December 12th, 1931, p 1103) it was mentioned in these columns that a copy of an early edition of Sir Thomas Elyot's "Castel of Helth" was to be sold a few days later at a London auction room and the phrase was added, not, of course, the first edition By a curious coincidence an actual copy of the hitherto unknown first edition of this celebrated book has at last come to light and is now offered for sale at £100 by The Salamander Bookshop, Ltd Silver Street Bloomsbury The *Dictionary of National Biography* contains the statement that one of the Harleian MSS is in the form of a dedicatory epistle to Thomas Cromwell which cannot be of later date than 1534 whence the inference has been drawn that the original edition must be of that year or previous to it This new find confirms the deduction as it is dated 1534 and is inscribed "Thomas Elyot knyght to the Right Honourable Thomas lorde Cromwell, lorde priuye seale" The title runs 'The Castell of Helthe, gathered and made by syr Thomas Elyot knyghte oute of the cheefe authors of phisyke, wherby euerye man maye knowe the state of his owne body the preseruation of helthe and how to instructe wel his physytion in syknes, that he be not deceyued" The last paragraph is, 'And of the erthe created medicyne, and the wise manne shall not abhore it Thus fare ye wel gentyl reders, and forget me not with your good reporte and praye to god that I be neuer waxe occupied" The same booksellers have also in stock other medical rarities For example a satirical medical play, published in London by Thos Harper in 1638, entitled, 'Cornelianum Dolium' by T R The sweating tub, also called Cornelius's tub was very much in vogue in the sixteenth century in the treatment of syphilis, and it is around this usage of the tub that the plot of the play revolves We are informed, however, that the author "has happily avoided mere ribaldry on the one hand, and pompous moral stricture on the other" The real authorship remains unsettled at various times it has been ascribed to Thomas Randolph, Richard Brathwait Thomas Riley and George Ruggle They have also a book by Daniel Becker of Leyden published in 1640 which describes a gastrotomy performed by the German surgeon Daniel Schwalbe for the recovery of a large knife which had been inadvertently swallowed by Andreas Grunheide a Prussian peasant Another exceedingly rare book (because most of the edition was burnt by order of the Inquisition) is T Campanella's "Medicinalium juxta propria principia libri septem" Lyons, 1635 notable for the description of rhinoplasty as practised by a Calabrian family of plastic surgeons There are several editions of the 'De Re Medica" of Celsus dated respectively 1516, 1528, 1549, 1566, 1625 Another valuable work is the first edition of Estienne's textbook of anatomy published at Paris in 1545 with sixty-two full-page illustrations this anatomist discovered the existence of the valves in veins and was also the first to trace blood vessels into the bones Finally there is a very early instance of what is usually nowadays called 'A System of —— by various writers" to wit, a treatise on syphilis by Peter Andreas Mattheolus, John Almenar Nicholas Massa, Nicholas Poll Benedict of Vittoria, and Angelo of Bologna all under the editorship of Joseph Tectander of Cracow Of these authors Massa was perhaps the most popular on this particular subject he advocated a combination of mercury and sarsaparilla This particular edition of the "Collectio Lugdunensis" was issued at Lyons itself in 1536 and is much rarer than the identical textbook published at the same time at Basel

NOTES ON THE HISTORY OF THE ASSOCIATION

THE British Medical Association founded at Worcester in 1832 by Sir Charles Hastings celebrates its centenary next July under the Presidency of Lord Dawson of Penn. In anticipation of this landmark in professional history the Council invited Mr E. Muirhead Little F.R.C.S. to undertake the task of annalist. We publish below the second of a series of advance extracts from the *History of the Association* which Mr Muirhead Little is preparing for publication at the time of the commemorative proceedings in Worcester and London.

SIR CHARLES HASTINGS

The founder and first secretary of the British Medical Association was born at Ludlow in Shropshire on January 11th 1794 the sixth son of the Rev. James Hastings rector of Butterley. The name of Hastings had long been a good one in and about Worcestershire and although the exact connexion between the rector and the great Warren Hastings of Daylesford cannot now be ascertained they were generally considered to be cousins and the two families were on friendly terms. Not long after the birth of Charles his father became rector of Madley near Worcester and there Charles was brought up. The school in the village appears to have had a good reputation attracting boys from a distance and at that school he received all his general education.

As a boy Hastings is said to have been devoted to an outdoor life and not to have been particularly studious but when his father broke down in mental health the large family found itself in some straits and Charles had to set to work. He was apprenticed to two surgeons Messrs. Jukes and Watson at Stourport Worcestershire who were well thought of in that neighbourhood and who with a view to his candidature for the house-surgeoncy of the Worcester Infirmary advised him to go to London for further instruction. He accordingly became a pupil at the celebrated Blenheim Street School of Joshua Brookes and attended lectures at Dr. John Taunton's private school besides those on medicine by Dr. Robert Hooper in Savile Row. It has been stated that he also received instruction from a Dr. Ager about whose activities we have been unable to learn anything. In the autumn of 1812 Hastings returned to Worcester. The contest for the post of house-surgeon in the Infirmary was severe but Hastings who was only 18 years old and had no diploma of any kind was successful by 184 to 168 votes notwithstanding the fact that his opponent was a much older and a well-qualified man. He justified his appointment by his care and diligence in taking notes and by his experimental work under Dr. A. P. Wilson Philip on the functions of spinal ganglionic and cerebral nerves. The results were communicated by Philip to the Royal Society and published in the *Philosophical Transactions*.

After three years of house-surgeoncy Hastings was advised to go to Edinburgh for a degree. There he soon joined the Royal Medical Society and took an active part in its discussions. He assisted in experiments on transfusion the results of which were published in the inaugural thesis of Dr. Leacock of Barbados. In the spring of 1817 he carried out an experimental inquiry into the action of the blood vessels in health and disease with a view more especially to demonstrate an independent contractile power inherent in the arterial capillary and venous systems. He was said to have been at that time the only student in the University who used the microscope in physiological and pathological investigation. In the same year he was elected president of the Royal Medical Society. In 1818 when he read an account of his study of the circulation in the frog's foot as seen under the microscope some speakers denounced such methods as useless and said that deductions drawn from experiments on the lower animals were very fallacious and that such investigations were indefensible in themselves.

While in Edinburgh Hastings attended Professor Jameson's lectures on natural history and the interest thus aroused in this subject never left him. He graduated in medicine in 1818 his thesis being *De vi contractili vasorum* and in the same year was elected physician to the Worcester Infirmary at the age of 24. This post he held for forty-four years resigning in 1862. He soon became and for long remained the leading physician in Worcestershire and in the surrounding counties.

From this short account it will be evident that Hastings was a man of considerable abilities some originality of mind and great industry. On his return to Worcester young as he was he seems to have been speedily accepted as a leader in medicine and in natural history. But he was not content to sink into the position of an ordinary country physician enjoying a large practice and that *otium cum dignitate* which he might so easily have obtained. His writings in the years between his establishment in Worcester and the foundation of the Association show that he was busy with his pen in setting forth his views on those topics in medicine and natural history which always interested him.

In 1828 with the view of raising the tone of provincial medical practice and supplying a medium for the interchange of opinion and the diffusion of knowledge Hastings started a quarterly journal *The Medical and Surgical Reporter and Topographical and Statistical Journal*. He had realized the need of a publication which

should make use of the valuable material available in provincial practice and more especially the clinical and pathological knowledge which was running to waste in the county infirmaries To this journal in the four years of its existence Hastings contributed freely The farewell address in the last number dated May 1832 stated on behalf of the editors that the great object of their arduous undertaking had been from the first not only the mutual instruction of the members of the profession but also the foundation of an association for the diffusion of medical knowledge

In 1832 Hastings called together a meeting at the Worcester Infirmary at which the establishment of the Provincial Medical and Surgical Association was decided upon He delivered an inaugural address at the first meeting and for many years he was secretary and the leading spirit of the Association skilfully guiding it through many difficulties At the meeting in Liverpool in 1839 a portrait in oils painted by Benjamin Rawlinson Faulkner which is now in the care of the solicitors to his eldest grandson at Worcester was presented to his wife The engraving of this portrait by S W Reynolds jun is fairly well known there is a copy of it in Martley Rectory and among others one signed by Hastings in the British Medical Association House in London From this portrait (reproduced herewith) the obverse of the Hastings medal and the medallion on the outer cover of the *British Medical Journal* is taken In 1843 Hastings resigned the secretaryship owing to its increasing duties and was appointed permanent president of Council and treasurer He was knighted in 1850 and when the General Medical Council was set up under the Medical Act of that year Hastings was appointed a member

His interest in public health was enduring He was president of the Section of Public Health at the York meeting of the Social Science Association When cholera was epidemic at Worcester he took a great part in removing the stricken poor to camps outside the city Sedentary occupations favoured the incidence of phthisis in Worcestershire and as early as 1820 he published *A Treatise on Inflammation of the Mucous Membrane of the Lungs* to which was prefixed an *Experimental Inquiry Respecting the Contractile Power of the Blood Vessels and the Nature of Inflammation* Hastings was an active member of the Worcester Natural History Society and assisted in founding and supporting the museum A portrait later than that by Faulkner hangs in the Victoria Institute Library and Museum Beneath it is the following inscription

Presented by Susanna Holvoake to the Worcestershire Natural History Society as a token of her regard for Dr Hastings one of the earliest and most zealous of its members and also as a mark of her respect and esteem for that useful and most honourable institution His book *Illustrations of the Natural History of Worcestershire* was published in 1834 and he subsequently published an account of the salt springs of the county a considerable part of which work was utilized by Sir Roderick Murchison in his *Silurian System*

Hastings did not share his family longevity he died at Barnard's Green near Malvern from carcinoma of the duodenum ending in perforation on July 30th 1866 aged 72 He had for many years been lame as the result of some injury to the hip sustained in a carriage accident but this lameness did not impair his professional activity He had married in 1825 the eldest daughter of Dr George Woodyatt physician to the Worcester Infirmary The issue of this marriage was an only son Mr G W Hastings who for some years was member of Parliament for East Worcestershire and acted as legal adviser of the Association on matters of medical reform With the consent of the trustees Mr Hastings generously placed the medical library of his father at the disposal of the profession in Worcester At a meeting held in October 1866 a cordial vote of thanks was passed by the members of the profession in the city and county the gift was accepted and it was determined to form a Medical Society The books were subsequently transferred to the library of the Association in London The bust of Sir Charles by Mr (afterwards Sir) Thomas Brock R A who was himself a native of Worcester was presented to that city by the Association at the Jubilee Meeting in 1882 and placed in the Victoria Institute Public Library The Sir Charles Hastings clinical prize for general practitioners of £50 was established by the Association in 1924 and was first awarded at the Annual Meeting at Nottingham in 1926

MEDICAL USES OF RADIUM

REPORTS FROM RESEARCH CENTRES

Reference was made in the *Journal* of December 12th 1931 to the Medical Research Council's publication on radium * The following account summarizes in greater detail the reports for 1930 from the Council's research centres and deals with the use of radium therapy in cancer and other malignant conditions as they occur in various sites in the body

CANCER OF THE BREAST

Forty cases have been treated with radium at the General Hospital Birmingham Keynes's technique being adopted in seven of the late cases The Marie Curie Hospital London has adopted the following methods of treatment for breast cancer (1) Radium alone needles under pectoralis major at base of tumour (with large tumours a second row above basal layer) treatment of wide surrounding zone with packs Glands surface irradiation or needle insertion with packs (2) Local excision with needle insertion at same operation Surface irradiation by packs before or after removal of needles (3) Radical operation and radium Needles into upper five intercostal spaces near the sternum at operation (4) Recurrence surface irradiation insertion plus packs x rays Seventy three cases treated since 1921 at the Middlesex Hospital show that the best results were obtained with radium used at as great a distance as 6 cm Considered as a local disease and treated in the early stages cancer of the breast appears to be usually responsive to suitably planned surface radium therapy An interesting case from the Royal Free Hospital illustrates the sterilization of a primary mass in the breast by insertion of radium needles Sections cut in a wide area four months after irradiation showed the tumour almost everywhere transformed into fibrous tissue Some microscopic areas of tumour cells were found on close examination to be necrotic At St Bartholomew's Hospital there has been a tendency to irradiate more widely around the breast tumour Follow up of cases suggests that patients who die of carcinoma die from distant metastases and that in almost all cases there has been great local improvement in or disappearance of the primary tumour

CANCER OF THE UTERUS

Cervix.—In the treatment of cervical cancer modifications of the Stockholm and Paris techniques have been used The Royal Infirmary Cardiff describes twenty five cases of fistula formation Expectation of life is longest in rectal next in vesical and least of all in double fistula At the London Hospital where technique conforms very closely with that of the Radiumhemmet deep x rays are only used for recurrence The Marie Curie Hospital finds that the use of supplementary external irradiation where the parametria are invaded and especially where there is fixation increases the number of five year cures obtained

* *Uses of Radium* Special Report Series No 160 H M Stationery Office (9d net)

Corpus—Out of twenty-five cases treated at Cardiff since 1923 only five are alive. The report of the Marie Curie Hospital is somewhat more encouraging. Technique has been recently altered, smaller intensive doses being given. Radon cylinders are placed in each commissure, radium tubes in tandem from fundus to internal os, and radium plaques in the fornices. X rays are given two weeks after treatment. Of forty-one cases treated since 1925 thirty-one are now living.

Mouth, Nasopharynx, Larynx, etc.

Mouth and Nasopharynx.—The Birmingham General Hospital, referring to the treatment of gland fields, notes that the date of appearance and extent of metastases bear no relation to the size of the primary growth. In cases where the glands are enlarged and inoperable the practice of removing part of an infected tissue in a large mass is present, followed by irradiation when the wound is healed, has been given up as useless. It is now found better to expose the growth by reflecting skin and subcutaneous flaps and to insert needles on a definite plan under the eye. One hundred and twenty-two cases have been treated since 1926, there being forty-three clinical cures, eight improved, seventeen not improved, and fifty-four deaths. Clinical cures have been obtained in the following percentages: (1) tongue (anterior two-thirds) 32, (posterior two-thirds) 24; (2) floor of mouth 15; (3) cheek and lip 52.

Larynx.—At Birmingham it has been found that the most hopeful sphere for radon seems to be in those very extensive septic inoperable growths of the pharynx and hypopharynx which tend to invade the larynx. Radon is preferred to radium needles owing to the retching and discomfort arising from the strings by which the latter are suspended. Radon seeds are inserted around the growth and a radium collar fitted carrying needles parallel to the sterno-mastoid muscle.

Oesophagus.—All cases of oesophageal cancer have been disappointing but one at University College Hospital showed improvement eight months after treatment.

Rectum, Bladder and Prostate.

Fifty cases of rectal cancer have been treated at the General Hospital, Birmingham, since 1926. Preliminary colostomy is carried out whenever possible. The usual technique is removal of the coccyx and lower part of the sacrum with insertion of needles around the growth, long needles being placed parallel to the meso-rectum. Unsatisfactory results are attributed to the fact that rectal cancer is much more radium-resistant than the squamous epitheliomata of the mouth. Further advice is sought late, there is a septic element, and the tumour is often inaccessible. The Marie Curie Hospital comments on the painful effects in some cases following the posterior barrage method of treatment. Out of fifteen inoperable cases this method was used in three, the remainder having surface application with or without local insertion of needles or seeds. Results are given in the comment. The majority have been improved, three for over two years. Thirteen are living, four are dead. At St. Bartholomew's Hospital, as a preliminary to excision of the rectum in inperitoneal radon is given to glandular areas at the time of colostomy. This is being adopted as standard treatment. Attention is drawn to a valuable new field for treatment—namely, the possibility of inoperable cases becoming operable as the result of radium therapy.

At St. Peter's Hospital out of fifty-eight cases of rectal cancer twenty-eight had insertion of radon seeds by proctoscope and thirty had open operation. As the extent of the growth cannot be determined by the proctoscope method this has now been dismissed as useless. In the open operation cases (a) probe, colostomy and barrel of needles; (b) patients did not benefit by the injection of 2 per cent. fluorescein into the tumour; (c) a combination of diathermy and radium has given immediate relief. None of the cases (all advanced) were cured, but there was relief of symptoms for six to eighteen months. It is interesting to note that a haemorrhage however severe can be controlled by a comparatively large dose of radiation of the whole malignant mass. For the prostate the technique of Herbst (suprapubic cystotomy and irradiation of bladder base and prostate from within) has been adopted, but it is early yet to give an opinion as to its value.

Brain Tumours.

The Royal Infirmary, Manchester, describes nine cases of hemispherical glioma treated during the last twelve months by external radiation. Two are in good health and able to work, two are dead, and one a complete invalid. It is concluded that gliomata are not very radio-sensitive, and that the accurate placing of needles is difficult, as is the avoidance of structurally important areas at the boundary of the tumour. The best method seems to be the combined use of radon and surface irradiation. At St. Bartholomew's Hospital experimental work on rabbits has disproved the old view that with large doses of radon any damage to cerebral tissue was secondary to thrombosis or haemorrhage. Though microscopical changes were visible after six hours' irradiation, and considerable damage was done to the cerebral tissue by the end of twenty-four hours, haemorrhage did not occur until this twenty-four hours period had been reached. Further experiments with radon seeds showed that though some damage to nerve tissue resulted, changes were neither so extensive nor so severe as to contraindicate the use of similar doses in healthy tissue in the vicinity of a cerebral tumour. It is assumed that the reactions of human brain tissue are similar to those of the animals.

Sarcoma and Lymphosarcoma.

Radium appears to have a useful place in the treatment of sarcoma. Of the thirty-three cases collected in 1931 there were 50 per cent. of good results in spindle-celled sarcoma, 41 per cent. in round-celled carcoma, and 23·5 per cent. in lymphosarcoma.

Nova et Vetera

A POPULAR PAMPHLET ON CHOLERA

In these days the outbreak of any new or uncommon disease is usually heralded by paragraphs in the daily press. In ancient times the priest was the natural vehicle of such information, since he was in close touch with his parishioners. Even in comparatively recent years, however, the rector of the parish was expected to be a guide to his flock in matters temporal as well as spiritual. The writer of this note has in his possession a pamphlet which was written by a clergyman to instruct his congregation in the *symptoms and methods of treatment* of the new disease, Asiatic cholera. The pamphlet is entitled:

Cholera Morbus. Precautions, Preventives & Remedies, compiled by a Clergyman for the use of his Parishioners.

It was printed in Doncaster and the preface is dated January 21, 1832.

Asiatic cholera had broken out for the first time in the British Isles in the autumn of 1831. The affected town was Sunderland, and the first death which was recognized to be due to true cholera occurred on October 26th. By the end of the year there had been 202 deaths from the disease in Sunderland, and shortly afterwards the disease died down there. On the Tyne, however, it had also broken out, and cases were numerous in this district. Other parts of England began to be affected in April, 1832. At Doncaster a fatal case occurred in a destitute tramping sailor in the beginning of January, but this led to no outbreak (Creighton). It seems very probable, therefore, that this pamphlet was inspired by the general perturbation occasioned by this fatal case.

The pamphlet consists of eight pages (about 2,500 words). It is bound in a paper cover. Apart from the preface the text may be divided into two sections. The

first section deals with precautions the signs of the disease and remedies This part is purely medical The second section of the text is theological and the thesis is supported by numerous Biblical references

The preface begins as follows

In collecting together the following Precautions Preventives and Remedies I have paid especial attention to the Circulars Reports &c which have been issued by the Boards of Health of London Other hints I have gathered from the Circulars of Local Boards from reports and remarks of Physicians and other papers to which I have had access The whole has been twice submitted to the inspection of an experienced medical friend to whom also I am indebted for many additional suggestions I had at first reference *to my own people only* but a friend expressed a wish that I would publish *for general information*

The first sentence of the preface refers to the Board of Health which was the outcome of cholera outbreaks abroad The disease had spread westwards into Europe and there had been severe epidemics in European Russia in 1829 and 1830 By the spring of 1831 it had reached Poland Hungary and the ports on the Baltic As a result a Royal Proclamation ordering various precautions was issued and on June 21st 1831, a Board of Health was gazetted in London Shortly afterwards several Local Boards of Health were formed voluntarily in different parts of the country

The section of the pamphlet which deals with precautions is especially interesting since it indicates the prevailing views on the etiology of the disease at a time when it was practically confined to one town in the North of England This section is quoted in full

The following *precautions* are especially addressed to the poor

1 —Have all nuisances such as manure *standing* and putrid water pig sties or anything which gives out an unpleasant smell *removed to a distance from your house* and keep all ditches and drains near you as clean as possible *My own people ought to know from sad experience how needful is this precaution*

2 —Limewash the inside of your houses *more frequently* than you are accustomed to do in times of general health This you know may be done at little expense and *it is of great service*

3 —Let your beds be filled with *fresh* straw and if you can procure another blanket

4 —When the weather is fine admit the air freely into your rooms

5 —Keep your houses yourselves and family as clean as possible changing your linen as often as you can *as often again as you used to do* and wash your feet once a week Cleanliness I do assure you cannot be too strictly attended to *it is of far more consequence than you in general suppose it to be and especially at this time*

6 —Avoid sudden chills be warmly clothed and be attentive to the strength of your shoes in order that your feet may be dry and warm *On no account sit down when your shoes and stockings are wet*

7 —Eat moderately and *if you value your lives* by all means *avoid spirituous liquors* and drink as little beer as possible Coffee morning and evening is better than tea Vegetables ought not to be eaten at all unless well boiled Greens may *not* be eaten turnips and potatoes may Tobacco and snuff are *not* preservatives against the cholera but rather *the contrary* the use of tobacco is indeed *extremely injurious* because it weakens the action of the stomach The use of broad flannel belts round the loins is strongly recommended also flannel waistcoats and petticoats

I now write not only for my *poorer* friends but for all and especially for those *who are far from medical aid* I am assured that if strictly and immediately attended to the means pointed out as remedies will by God's blessing prove successful

It is obvious that these precautions are wide of the mark so far as the real cause of cholera is concerned but they deal excellently with the predisposing factors In the three months during which the disease had been prevalent in Sunderland it had been shown that general sanitation played an exceedingly important part in the spread of the disease Writing of this Sunderland outbreak Creighton says The virus for all its opportunities showed a marked preference for, an almost exclusive selection of the lowest and least cleanly localities and a considerable preference for persons of drunken or negligent habits ' It was left to Sir John Simon to inaugurate the sweeping sanitary reforms which were to militate largely against any epidemic

The author of the pamphlet seems to be fairly near the truth when he states that vegetables ought not to be eaten at all, unless well boiled The qualifying statement— Greens may *not* be eaten turnips and potatoes may ' —shows however that the suggestion is really far from being accurate If we are to believe the statements he makes in his preface this opinion is probably a reasonable exposition of the scientific views of the time In point of fact although the part played by cholera infected water was not fully stated until 1849 when Snow published his pamphlet entitled ' The mode of communication of cholera ' at least one writer made a shrewd guess at the true mode of spread This writer (John Parkin) in a paper on the Cause nature and treatment of cholera, concluded that the disease was due to a poison generated in the earth this poison became diffused in springs and swallowing of the infected water produced the disease

The second section of the pamphlet— Signs of the disease ' —is as follows

Sudden loss of strength—the skin becomes cold and changes to a bluish colour—the voice is almost lost and becomes like a whisper—convulsions of the hands and feet take place—with frequent vomiting and looseness

For brevity and accuracy it would be difficult even to-day to better this description

The third section, which deals with Remedies is introduced by the following remarks

The objects to be gained are to make the sick person very warm to restore *the circulation of the blood* and *to get rid of a large quantity of bile which is on the stomach*

The author insists that the patient should be immediately wrapped in hot blankets and put to bed since the retention of the upright posture is liable to cause death The means advised for keeping the patient warm are rather heroic in the light of modern practice Poultices to the soles of the feet to the palms of the hands and to the stomach heated bricks bags of heated bran, corn or sand—these are some of the suggested methods

The giving of a large quantity of common salt in hot water as an emetic at the commencement of the illness is analogous to the modern method of washing out the stomach Where muscular spasms are in evidence the author recommends hot brandy and water or a teaspoonful of sal volatile in a cup of hot water repeated every quarter of an hour He adds naively I believe the last of these is the better It would be interesting to know whether his medical friends endorsed that opinion In severe cases laudanum is recommended as an addition to these remedies As a laxative for persons not affected with cholera he deprecates the use of salts or any cold medicines instead he recommends rhubarb and ginger or rhubarb peppermint and laudanum

Finally the author points out that the remedies which he has suggested are only intended to be used until a doctor is summoned

England and Wales

Liverpool University Jubilee Celebrations

The formal celebration of the fiftieth anniversary of the foundation of the University College of Liverpool was held on December 18th 1931 the Chancellor (Lord Derby) presiding over the degree ceremony at St. George's Hall. An Address of Commemoration was delivered by the Vice-Chancellor (Dr. Hetherington) and the Principal (Canon Rendall) gave a formal recital of the long roll of nearly sixty benefactors to whom the College and the University owed so much of their material existence. In his address the Vice Chancellor said that Liverpool University could trace its real origin to the foundation of a medical school in the town in the earlier part of the eighteenth century. The school was able to conduct official examinations and there was certainly organized medical teaching in the city before 1800. By 1900 there were nearly 600 students and in 1903 when the College became an independent University it had 645 day students. The students now numbered 2,200 and the annual expenditure was over £200,000.

Professor Blair-Bell Presentation Portrait

The annual dinner of the Liverpool Medical Students' Debating Society was held at the Adelphi Hotel on December 16th 1931 when Emeritus Professor Blair-Bell was presented with his portrait in oils to mark his retirement from the chair of obstetrics and gynaecology. In acknowledging the gift Professor Blair-Bell said that he hoped the portrait would one day hang in a hall belonging to the medical students who formed such an important unit in the University. Mr. J. A. A. Berne the painter of the portrait also responded to the toast of "Our Guests." Mr. Frank Jeans replying to the toast of "The President and the Staff of the Medical School" said that the medical students had been the backbone of the University. On behalf of the Medical School staff Professor Leith Murray paid a warm tribute to Professor Blair-Bell's valuable work in connexion with the British College of Obstetricians and Gynaecologists.

London Jewish Hospital Medical Society

The third annual dinner of the London Jewish Hospital Medical Society took place on December 10th 1931. Lord Moynihan of Leeds was the guest of honour and the chair was occupied by the president Mr. Maurice Sorsby. Nearly 400 members and friends were present. In a witty and able speech Mr. H. S. Souttar proposed the health of Lord Moynihan. In his response Lord Moynihan recounted some of the fortunate accidents which started him in his surgical career. British surgery which was second to none had been almost unknown outside these islands and it was with the object of proclaiming its due merits to the world that he had initiated the *British Journal of Surgery*. He had also contributed to the break-up of provincialism in surgical practice by founding the Association of Surgeons of Great Britain and Ireland. Viscount Erleigh proposed the toast of "The London Jewish Hospital" which in his opinion compared very favourably with any London hospital of a similar size. He was convinced that the notable intellectual integrity of the Jew would impart him to a marked contribution to the development of medical science in this country. Dr. A. Goodman Levy in responding suggested the remarkable progress that the hospital had made in the seven years of its existence. Arrangements would shortly be made for the holding of post-graduate courses there and he thought that the hospital would provide opportunities for Jewish doctors in this country to equal the achievements of their illustrious brethren abroad in imprinting their names upon the history of medicine. He emphasized the mutual advantages accruing to hospital and doctor through the agency of the society. Dr. I. Barnard proposed the health of the visitors in an amusing speech. Professor H. Levy who responded pointed out the need for keeping reliable Jewish statistics and records if human knowledge was to benefit from the biological experiment which Jewish distinctiveness constituted. Mr. B. Horwitz proposed the toast of "The Society and its President" and Mr. Sorsby replied.

Non-residential Allowances to L.C.C. Medical Staff

The scales of salaries and conditions of service of whole-time subordinate medical staffs in hospitals under the London County Council provide that in addition to their cash salaries such officers should receive emoluments of board lodging and washing valued at £150 a year and that generally speaking all assistant medical officers should be required to be resident. In any case the question of an assistant medical officer being non-resident should arise the primary consideration should be the interests of the service. It has been decided to fix the amount of the allowance to be made in lieu of residential emoluments to medical officers. Such an officer not regularly required to sleep in the hospital is to be granted an allowance equal to the full cash value of his emoluments—that is £150 a year—but where a room at the hospital has to be reserved for him in order that he may regularly sleep there a deduction of £20 a year from the full value of the emoluments is to be made. It is also proposed that non-resident medical officers who are receiving allowances in lieu of residential emoluments shall pay for any meals taken at the hospitals in accordance with the charges at present operative. These proposals apply only to medical officers who accepted the new scale of salaries and conditions of service fixed on March 3rd last. Permission to live out will not be granted unless the accommodation is required or can be utilized for other purposes.

Medical Treatment of London School Children

The medical and dental treatment of school children under the arrangements made by the London County Council for the year commencing April 1st 1932 includes provision for 2,150 eye cases, 21,380 ear, nose and throat cases, 488 ringworm cases, 78,210 cases of minor ailments and 147,070 dental cases. This is a slight increase upon the number authorized for the present year but the total expenditure (£116,189) is about £1,000 lower. It is reported that there is a gradual elimination of ringworm cases amongst the school population justifying a further decrease in the annual provision under this head. The scheme under which children suspected of being rheumatic or requiring observation for rheumatism are dealt with at certain hospitals and treatment centres continues to be greatly appreciated by parents. Under the scheme for next year arrangements have been made for cases to be dealt with at seven hospitals and eight centres where the Council's assistant medical officers will attend. There are at present ten special ear centres where operation treatment of children suffering from discharging ears is carried out. Provision has been made for two additional centres. The standard charge made by the Council to parents in respect of medical and dental treatment is two shillings a case and for minor ailments one shilling. All children operated upon for tonsils and adenoids are now detained in the various centres as in patients and the cost to the Council averages 17s. per case but the parents have hitherto been asked only to pay two shillings. It is now proposed that their contribution shall be raised to five shillings.

Scotland

Edinburgh Health Exhibition

A health exhibition to be held in the Waverley Market Edinburgh in aid of the Royal Infirmary of Edinburgh Bicentenary Extension Appeal Fund will be opened on January 27th by Sir James Barrie The general organization of the exhibition is under the superintendence of Dr William Robertson former medical officer of health for Edinburgh and a surgical exhibit to include various interesting historical relics of surgery as practised by Lister and in pre Listerian days is being prepared under the supervision of Dr Logan Turner The radiological department of the Royal Infirmary is to have a large exhibit illustrating the work of the department it will include photographs of foreign bodies broken bones and disease processes and also appliances illustrating the method of using radium The Edinburgh Corporation Gas and Electricity Departments will exhibit model sickrooms with various lamps used in treatment

Obligations to Hospitals

At a bazaar in aid of the Edinburgh Royal Infirmary Extension Appeal Fund held recently at Cowdenbeath Fifeshire and opened by the Right Hon William Adamson late Secretary of State for Scotland the need for extended accommodation at the Royal Infirmary was emphasized Mr Adamson pointed out that the population of Fifeshire had a special obligation to support this institution There were in the county several local hospitals excellently equipped and staffed and as an outcome of the special effort made in West Fife last year £50 000 had been raised for the extension of the Dunfermline and West Fife Hospital by an extra forty beds This hospital and the local hospitals at Kirkcaldy and Wemyss were taxed to the limit of their capacity and despite these facilities the demand for beds in the Edinburgh Royal Infirmary by patients from Fifeshire continued One in seven of the patients treated in the Edinburgh Royal Infirmary came from Fifeshire the total number sent from this county being greater than that from any other county in Scotland and second only to that from the city of Edinburgh In the past year 2 248 of the patients treated came from Fife and it might be computed that these cost the institution for maintenance not less than £16 000 per annum The total subscriptions received from the county however from all sources in the course of the year amounted to £4 500 this averaged about £2 per patient while the cost to the institution had been not less than £8 per patient

Longmore Hospital, Edinburgh

At the annual meeting of subscribers to the Longmore Hospital for Incurables Edinburgh presided over by General Sir Robert Gilmour Bt, the chairman of the board of managers in moving the adoption of the report said that the average number of patients in the hospital during the past year had been 208 of whom many were completely helpless There had been a waiting list of 209 patients of whom it had only been possible to admit 126 and it was a sad fact that many of the applicants died before beds could be found for them The number of deaths during the year had been 103 of which between 50 and 60 were of patients who had been admitted that year It was satisfactory to note however that some cases had yielded to successful nursing and treatment and had been discharged as no longer requiring hospital treatment The most obvious need of the hospital was for increased accommodation for the treatment of cancer cases during the year 62 patients suffering from cancer had been admitted although the cancer wards contained only 27 beds Efforts had been made to effect economies of administration the cost per bed per annum had now been brought down to £90 but it appeared that little more saving could be effected consistently with efficiency Professor Edwin Bramwell in seconding the adoption of the report said that a hospital of this kind for incurable cases would probably always be needed, notwithstanding the fact that important discoveries in medicine were being made from day to day Tuberculosis was no longer the scourge that it had been and two diseases—pernicious anaemia and diabetes—which were at one time always fatal had within the last few years come under control It was therefore reasonable to hope that in the not far distant future some relief might be found for cancer and also for two diseases of which there were always a number of cases in hospital wards—namely disseminated sclerosis and rheumatic disorders This hospital was doing a great work for which the citizens of Edinburgh could not be too grateful

Health of Aberdeen

A report was submitted at the meeting of the Public Health Committee of Aberdeen County Council on December 11th which had been drawn up by Dr Rae chief medical officer of health and Mr H L Fraser county clerk of Aberdeenshire It contained a scheme for dealing with hospital provision in Aberdeen and suggestions for the better utilization of homes and hospitals in the counties of Aberdeen Angus Banff and Kincardine The chairman of the committee, Mr C W Sleigh in explaining the scheme pointed out that the suggested changes were highly desirable in view of the new powers which county councils possessed under the Local Government (Scotland) Act of 1929 It would have the effect of concentrating certain classes of cases in certain institutions instead of varied cases in each hospital or institution as at present It was agreed that in view of the general financial position at the present time the question of the arrangements which would ultimately be made for the care of adult mental defectives should be postponed It was also arranged that a conference should be held between representatives of the Aberdeen County Council and the Kincardine County Council to discuss the question as to whether provisional arrangements might be made with the object of ultimately enabling Maud Home and Stonehaven Combination Home to become 'one purpose' institutions providing for cases from both counties

District Nursing in Scotland

At the annual meeting of the Scottish Branch of the Queen's Institute of District Nursing the Countess of Mar and Kellie congratulated the Scottish branch on the great extension of its work which had taken place during the forty three years of its existence The branch began with two nurses and now it had 953 nurses working under its supervision These nurses carried an atmosphere of comfort and assurance into the homes which they visited and their work obviated the necessity for many thousands of beds in hospitals which were already full and often had large waiting lists The Countess of Minto delivered an address dealing with the Gardens Scheme organized in aid of the branch from which a sum of £1 100 had been derived during the past summer Owners of gardens throughout the country had permitted the public to visit their grounds on payment of a small fee which was handed over to the institution The scheme had been introduced into Scotland last April 263 gardens had been open to the public in this way and approximately 36 000 people had visited them A still more satisfactory result was expected next summer

Glasgow Medical Missionary Society

At the annual meeting of the Glasgow Medical Missionary Society held on December 10th Sir Steven Bilsland Bt presided and said that the society had carried on a most important work for the physical and moral welfare of the citizens of Glasgow The report showed that 41 384 patients had attended at the dispensaries during the year an increase of 2 095 on the previous year and that over 240 visits had been made by the superintendent and his assistant and over 600 by nurses Bible-women had also made 3 491 visits to the homes of sick persons while a large number of coal and food tickets received from the Sir Thomas Lipton Fund had been distributed among the poor The ordinary income of the society for the year had been £87 less than the expenditure and an appeal was made by the chairman for additional contributions

Miners Convalescent Homes

A set of ultra violet lamps has been installed at the Saltcoats Miners Convalescent Home This is the first convalescent home for miners in Scotland to make use of these lamps and it is proposed that similar facilities for ultra-violet ray applications should be installed at other convalescent homes pithead baths and similar places where miners who spend a large part of the day underground will be able to obtain this artificial substitute for sunlight It is also announced that the Miners Welfare Committee has under consideration the provision of a new convalescent home to accommodate 100 persons the present home at Saltcoats would then be used for miners dependents

India

Unlegalized Practice and Qualifications

The Government of India has under consideration a proposal to add a fresh section to the Indian Medical Degrees Act penalizing a practitioner who adds to his name letters or abbreviations which imply that he is qualified to practise any system or method of medicine other than letters or abbreviations indicating qualification which are recognized by any law for the time being in force in British India or in any part thereof and which have been granted by any authority recognized by the Act The fine to be inflicted for a first offence of this kind or for adopting indications of qualifications other than those actually possessed may extend to 500 rupees subsequent offences being punishable by a fine of up to 1 000 rupees At a meeting on September 26th 1931 the Bombay Medical Council resolved to inform the Government of India that while accepting this proposal it considered it to be only a half measure inasmuch as while penalizing persons assuming such titles it left these bogus institutions (even overseas institutions) which granted such titles or diplomas free to carry on their trade and so to deceive the public The Council added that unless and until the amendments drawn up in 1926 by the Legal Remembrancer to the Government of Bombay were embodied as additional amendments the existing unsatisfactory condition of unqualified and unlegalized practice would continue to prevail inflicting serious harm on the ignorant and even on the educated public and endangering health and lives It was stated also that the evil of which complaint was made in 1926-27 had become greatly aggravated in almost all the principal towns of India thus emphasizing the urgent necessity for amending the act along the lines suggested

Anti malarial Measures in Travancore

Lieut-Colonel W W Clemesha I M S has contributed to the November issue of the *Indian Medical Gazette* a further instalment of his account of the anti malarial work which is in progress on the estates of the Travancore Tea Companies in the Vandiperiyar Valley For four years anti gametocyte measures were adopted as regards the children en-quinine and thus being used until the end of 1929 In the two following years the children were found to be free from parasites and such measures were no longer necessary the few children with enlarged spleens were treated on these lines during the malaria season With the aid of a statistical table the value of the plasmoquine after-treatment is demonstrated Until the end of June 1929 the annual percentage of malarial cases was never less than about 20 per cent an annual figure of 45 per cent being often reached in spite of the initiation of anti-larval measures and the treatment of children Within twelve months of the introduction of the plasmoquine anti gametocyte after-treatment which was started in the autumn of 1929 the proportion of malarial patients throughout the year was in the neighbourhood of 10 per cent and within two years it had been still further reduced—sometimes to as low as 2 per cent In three out of five estates the maximum percentage malarial sick rate for the last year was under 3 even though highly infected gangs of coolies had been introduced from elsewhere without proper treatment on arrival at Travancore Colonel Clemesha insists that the proper way to stop infection from malaria is to lessen the anopheline population and the gametocyte carriers simultaneously and that the anti gametocyte after-treatment is a satisfactory and easily performed method of reducing to very small proportions the number of gametocyte carriers in any community

Government General Hospital Madras

In 1930 there were 88 299 new out-patients and 14 918 in-patients treated at the Government General Hospital Madras as compared with 76 711 and 13 595 respectively in the previous year the number of beds being only 554 of which 168 are reserved for women and paying patients there was always a condition of overcrowding especially on the Indian male side Clinical instruction was given to 358 medical students in the various departments of the hospital As is usual in the annual report of this institution considerable space is provided for records of cases of special interest Locomotor ataxia seems to be moderately common in Madras among Indians six cases were admitted during the period under review two of the patients having juvenile tabes A Hindu girl aged 8 was found to have congenital dislocation of the hip there was no history of antecedent syphilis Another patient aged 16 had had a right ischio-rectal abscess all his life which at any symptoms until an active endocarditis ended with a fatal termination Out of 182 cases of sepsis complicating pregnancy there were three of acute Bright's disease but this complication was not found in simple sepsis A duodenal ulcer of the post was discovered in one of the surgical wards prompt improvement followed the administration of anti-diphtheria serum Diathermy associated with radiant heat and ionization proved very effective in chronic polyarthritis of rheumatic origin In the Government Venereal Institute 71 000 patients were treated in 1930 as compared with 51 000 in 1926 though there was no change in the number of the staff The hospital is being remodelled and extended in view of the demand on its accommodation An administration block was constructed during 1930 and a pathological institute for the medical college The nursing staff quarters are being enlarged

Correspondence

OCULOGYRIC ATTACKS IN CHRONIC ENCEPHALITIS

SIR —I am grateful to Dr Ranyard West for his kind letter in the *Journal* of December 12th 1931 and for the interesting points which he has raised It is perhaps somewhat difficult to reconcile the distressing excitement which often accompanies an oculogyric attack with the peaceful calm of normal sleep but these are the two extremes The ocular attack may after a short and stormy onset pass into peaceful slumber whilst ordinary sleep after a quiet start may become anything but calm and restful

Dr West refers to the occasional attacks of complete immobility of various groups of muscles whilst performing some voluntary act and mentions a case in which these are accompanied by ocular crises Although coincident the two are probably distinct phenomena because similar ocular attacks occur in cases in which general muscular rigidity is minimal and immobility unknown whilst conversely many cases with extreme rigidity never have ocular attacks Further, the doings in the two sets of muscles concerned are not at all comparable The limbs become so to say frozen ' at a certain point in an uncompleted action whilst in an ocular attack the eye muscles act in a way unknown in ordinary vision It is no uncompleted action but a movement which so far exceeds normal that it prevents vision

It seems more probable that in Dr West s case the emotional excitement brought about by the immobility is the immediate cause of the ocular attack As a rule the comparative mobility of the eye muscles in Parkinsonians is in striking contrast with their general immobility in other parts but occasionally cases are seen in which the patient tells you that he gets his eyes fixed on an object and cannot move them These seem to belong to the same category as the attacks of immobility to which Dr West refers but they are quite distinct from oculogyric attacks Debove in 1878 described a similar thing in a case of paralysis agitans in which the woman could not get her eyes back to the beginning of the next line when she had read to the end of the preceding one whereas so far as I know there is not a single record of oculogyric attacks in paralysis agitans

As regards the question of ' active spasm of the lids I do not know whether Dr West refers to actual closure of the lids or merely a spasmodic fluttering If the former I have referred to it in detail in the lecture (*British Medical Journal* November 7th 1931 p 837) if the latter it is a very frequent accompaniment of the onset of attacks during the stage when excitation and inhibition are struggling for the mastery

He refers to the flexion of the neck in the patient with the eyes turned down It seems to be the rule in these attacks that the position of the eyes determines the position of the head When they are up the neck is extended when down flexed when to one side inclined laterally Also any combinations of these eye positions give rise to a corresponding obliquity of the head These seem to be associated muscular actions which are habitually called forth when the eyes are voluntarily turned in any given direction in ordinary life

Perhaps the difficulty in connecting these attacks with sleep may be less if the terms are more clearly stated If we accept Pavlov s views that sleep is generalized inhibition then normal or whole sleep is such a state of inhibition which has spread all over the cortex and such other parts of the nervous system as is necessary It stops short at a certain point it can be carried further by narcotics It can also be incomplete as in the various stages of going to sleep, waking deep and light sleep nightmares somnambulism and so forth If we accept Pavlov s theory, sleep and inhibition are synonymous terms and a localized inhibition is a localized sleep

The oculogyric attack may be such a local inhibition in those areas from which so long as the eyes are open stimuli should constantly be streaming forth to the extrinsic eye muscles In normal life the resulting tone in the eye muscles never ceases except when the lids are closed , when they close, it does cease, and it is absent throughout sleep Further as I have shown in my lecture during sleep the position of the eyeballs is as various and as bizarre as in any oculogyric attack, and this is a state of general inhibition when the muscles are at rest We do not close our eyes for any length of time except when going to sleep so that a change of activity in this hypothetical area or areas connected with eye closure and consequent rest of the eye muscles is not only intimately but one may say almost solely concerned with the acts of sleeping and waking In the sufferer from oculogyric attacks, that part of the area which controls the supply of tone to the eye muscles is too readily exhausted, and passes into a state of inhibition under all sorts of nervous disturbances whereas it should remain in full activity until such time as the closure of the lids inhibits it

In conclusion, may I point out that although Dr West puts " release phenomena ' in inverted commas it is not a quotation from my lecture because I was careful not to use the expression throughout —I am etc

Sheffield Dec 20th 1931 ARTHUR J HALL

THE SOURCE OF INFECTION IN AN OUTBREAK OF PUERPERAL FEVER

SIR —There is an important point in Dr Paine s interesting and valuable report of a small outbreak of puerperal fever (*British Medical Journal* December 12th 1931, p 1082) to which he himself does not draw attention

If as appears very probable, the haemolytic streptococci were transferred to Case II from the throat of Nurse C that transfer must have occurred *after delivery* since the records state that this nurse was not on duty till 6 a m and delivery took place at 4 a m

In discussions on the etiology of puerperal infection it is often assumed that in the case of normal confinements in which no vaginal examinations have been made—and especially in cases of precipitate labour when neither doctor nor nurse is present—the infection must necessarily have been an autogenous one—that is derived either from the patient s genital tract or from some other part of her body It does not occur to those who use this argument that infection may quite well take place after delivery In cases of precipitate labour where there is an element of emergency it must surely often happen that a well meaning but ignorant neighbour or relative commits just those sins against surgical cleanliness which serve to convey the seeds of infection

For many hours after delivery there is serous fluid oozing from the placental site so that the whole genital tract from fundus uteri to vulva affords a favourable breeding ground for haemolytic streptococci implanted at any point If that is agreed it surely constitutes a case for the use of masks by all nurses when changing pads passing catheters etc during the first three or four days of the puerperium —I am etc

Queen Charlotte s Hospital Research Laboratories Dec 20th 1931 LEONARD COLEBROOK

40 000 units intravenously and 40 000 units intramuscularly the intramuscular dose being repeated in twelve to eighteen hours Dr Grundy states that many dangers attend the intravenous method, and I may therefore add that in none of these cases did anxiety arise from its use Provided the needle be sharp and the technique satisfactory it is less painful and little more dangerous than the intramuscular route while it is supported by clinical experience and experimental evidence

One may agree that the dosage at Hospital A appears to be on the low side Nevertheless in my opinion percentage mortalities in the region of 2 66 are merely an indication that the disease is of a relatively mild character, and cannot rightly be attributed to the use of any particular system of dosage —I am etc

December 22nd 1931

GENITO URINARY TUBERCULOSIS

SIR —In Professor Burgess s interesting and instructive J B Murphy Oration published in your issue of December 19th 1931 we read that in Murphy s opinion early renal tuberculosis can be cured by non operative measures prominent among which he placed the injection of tuberculin Murphy s views were based upon experience and I have practised and preached this method for thirty years In 1909 I wrote in my book on tuberculin (p 109)

In suspicious cases of chronic pyelitis or of renal trouble I have used the tuberculin test in diagnosis and am astonished that so many writers in discussing the diagnosis of renal tuberculosis overlook the tuberculin test Not only is tuberculin of very great value in the early diagnosis of renal tuberculosis which so often runs a latent course even for years but renal tuberculosis in my experience seems to be particularly amenable to tuberculin treatment This field is waiting to be exploited by the searchlight and touch of tuberculin

For nearly thirty years I have consistently used tuberculin as a remedy in many cases of genito urinary tuberculosis—all of them advanced cases with tubercle bacilli in the urine I have always used large doses about 1 c cm or more of the strong preparations and (except in one case of a young boy aged 12 who had had the disease for many years and ultimately died of anuria due to the extensive destruction of renal tissue) with uniformly good results In my book (p 315) I report

In November 1902 a case of genito urinary tuberculosis sent to me by Sir Herbert Maitland a man of 50 weight 11 st 5 lb Began in testis and spread to bladder and kidneys Lungs also affected Sir H M found by cystoscope numerous (six) ulcers on surface of bladder Urine Deposit of pus two inches in depth containing millions of tubercle bacilli—great dysuria—cannot hold urine an hour — lungs also affected Treated with T R — many reactions—103 4 102 (0 85 c cm T R)—then T E Treated for a year 1907 Urine absolutely clear no albumin—no pus but prostatic trouble causing obstruction Sir H M opened bladder and removed portion of prostate—saw the scars of old ulcers—weight 13 st Sir H M wrote to me—A living illustration of the value of tuberculin

Most of the patients have been treated at my clinic as ambulant cases—coming from various hospitals At present four such cases come regularly to the clinic for treatment In one case of combined renal tuberculosis (one kidney removed by Mr Hurry Fenwick) and phthisis of many years duration with numerous tubercle bacilli in the sputum first treated by me in 1911 the patient is still alive and active—and the sputum has ceased Indeed the results in the advanced cases of renal tuberculosis have been so striking that I am bold enough to think with J B Murphy that as in the case of tuberculosis of the testis removal of the organ for apparent unilateral renal tuberculosis will be found to be unnecessary as soon as it is realized that in early renal tuberculosis tuberculin alone will arrest the disease and do away with the necessity of extirpation One great advantage of tuberculin treatment is that if both kidneys are tuberculous tuberculin acts upon both kidneys and arrests the disease I venture to say that at any rate removal of one kidney is not wise or reasonable till tuberculin given ultimately in large doses, has had a thorough trial If good results can be obtained by means of tuberculin in late cases of renal tuberculosis it is relatively easy to arrest the disease in the early stages The following history speaks for itself

Dr M E Bowlby reported to me an extraordinary result in a case treated with tuberculin under my direction The patient had suffered long from renal tuberculosis The urine was thick with pus and contained vast numbers of tubercle bacilli She had been bed ridden for three months when I saw her and began treatment In 1922 nine years after treatment Dr Bowlby wrote thus 'For the past five years the patient has been wonderfully well considering both kidneys were affected and this year was taken ill in Switzerland and had to go into M Perret s clinique He would not believe that both kidneys were affected and intended to remove one but found on opening it that it was entirely cured—a thing that happens to one in a thousand'

—I am etc ,

London W Dec 21st 1931 W CAMAC WILKINSON, M D

VASO LIGATION IN PROSTATECTOMY

SIR —Professor Burgess in his interesting address Murphy and some principles of urinary surgery refers to the value of division of the vas deferens for the prevention of epididymitis following prostatectomy and states that he has carried out this technique since 1922 I believe I was the first surgeon in this country to perform vaso ligation as the routine procedure in prostatectomy as is shown by my hospital records for the year 1921 I certainly wrote the first article on this subject to appear in a British journal (vide *British Medical Journal* December 1st 1923) —I am etc

London W 1 Dec 21st 1931 CLIFFORD MORSON

RECOVERY OF VISION

SIR —Mr Norman Fleming s interesting case on 'Recovery of vision after twenty seven years' raises two questions which are very seldom possible of discussion in a Western country where cases of blindness are usually dealt with at an early stage but which are much more common in the East owing to the large number of blind people who either cannot or will not seek medical advice These are (1) the possibility of recovery of vision in late cases and (2) the method of recovery

Many years ago I removed two Morgagnian cataracts from a yogi of great sanctity in India He had been totally blind for thirteen years In one cataract the nucleus was a mere lamella in the other it was not found He recovered excellent sight and the effect in the district was profound but the sight took some days to come back At that time I was not fluent enough in Tamil to trace the steps of recovery but it was clear that the vision only came back by degrees getting more and more perfect as the days went by

Later in England in 1923 I performed iridotomy on an officer who had been totally blind for nearly six years as the result of the explosion in the breech of a machine-gun The case was published and commented on in the *British Medical Journal* of July 5th 1924 From stony blindness beforehand he passed through perception of light dim movement of objects and so on up to being able to read the daily press and to get about like the ordinary-sighted man To quote from my paper above mentioned

One is reminded of the way in which a foreign language learnt in childhood comes back gradually to a man when he revisits the country in which he learnt it The stored

impressions of earlier years gradually reawaken under the influence of the renewal of the old stimulations which originally evoked their storage in the cerebral cortex

In the eighth chapter of St Mark there is the account of the healing of a blind man whose first efforts resulted in his seeing men as trees walking and who later saw all men clearly The clinical record left by the New Testament writer is in accordance with all that modern observation from time to time reaches us of the gradual recovery of sight in long standing cases —I am etc

INTRODUCTION OF LIPIODOL INTO THE LUNGS

SIR—I have read with interest Mr Philip Franklin and Mr Alexander Ortel's article on a simple technique for introducing lipiodol into the lungs which appeared in the *British Medical Journal* of November 7th 1931 I can hardly agree with Messrs Franklin and Ortel however concerning the disadvantage of the aspiration of lipiodol *after cocainization of the laringo-pharynx* It has not been my experience in over two thousand bronchographies that inevitable partial swallowing of the oil and the difficulty of a uniform distribution of oil throughout the bronchial tree occur if the bronchography is properly performed Possibly the reason that Mr Franklin has had difficulty in preventing swallowing of the oil is because the cocainization of the pharynx has been too extensive In my own series of cases I have limited the cocainization to the anterior surface of the anterior tonsillar pillar and with but few exceptions have had no difficulty in producing a satisfactory bronchogram The method is extremely simple and one which is not objected to by any patients The technique advocated by Messrs Franklin and Ortel however has a distinct advantage in those cases in which a filling of the upper lobe bronchi is desired because with the aspiration technique the filling of the upper lobe bronchi is extremely difficult —I am etc

[illegible]

ALLERGY AND THE PROTEOSE

SIR—I have read with much interest the letters of Dr Freeman Barber and Ortel on this subject as I have recently been investigating the urticarial proteose in skin cases under my care Since only few control investigations have been published by the authors of this work I determined to investigate a series of normal persons as well as those suffering from skin diseases in which an allergic factor may be suspected—such as chronic urticaria angioneurotic oedema eczema of internal origin Besnier's prurigo and asthma and psoriasis

In the first place I am studying the relative amounts of proteose excreted by the normal person and by patients suffering from these conditions It is admitted that some proteose is excreted in health but it has been stated that much more is found in cases of allergy By using a constant technique I have noted that although slight variations in amount are found in different persons and in the same person at different times the amount excreted by normal controls and allergic patients is the same In all cases twenty four hour specimens were used

With regard to tests for sensitization I was greatly interested in Dr Barber's work on intradermal sensitization and should like to know what dilution of peptone was used for the production of the patch test on the same arm I cannot but feel that it was unfortunate that Dr Freeman's difficulties were not due to an account of this work for as he states in his last letter all the claims of proof of the specific action of proteose have been based on the intradermal reactions and apparently Dr Ortel still bases his arguments on these tests Our work has so far been limited to the study of the intradermal reactions

In my cases intradermal injections of 0 1 c.cm. of a 1 in 1 000 solution of proteose (Merck) control injections of 0 1 c.cm. of normal saline (we give but recently I have used a 1 in 1 000 solution of peptone made up in the same way as the proteose solution With regard to the interpretation of the results of these tests (an alteration in size of the wheal made by the injection) has been used to determine the result of the reaction employing Ortel's glass slide technique A negative reaction is one which faces without any increase in size of the wheal and vice versa Of eleven normal persons investigated in this way ten gave negative reactions to proteose while one gave a strongly positive reaction In three cases where the peptone solution was used as a control each gave negative reactions also Of fifteen patients suffering from skin diseases in which allergy was believed to be present eleven gave positive reactions and four gave negative reactions Of the seven negative cases two controlled with peptone with the following results In three the peptone and proteose gave equally positive reactions in two the peptone gave a more marked reaction than the proteose in two the peptone and proteose both gave negative results while in one case the proteose gave a positive reaction and the peptone a negative In one case—a patient suffering from chronic urticaria—I found that 0 1 c.cm. of a 1 in 1 000 solution of proteose (Merck) gave a development of urticarial wheals over the injection of saline produced no effect I now find however that a similar reaction is produced by an injection of 0 1 c.cm. of a 1 in 1 000 solution of peptone and the reaction cannot therefore be recorded as a proof of the specific nature of the proteose as I had originally believed

It would appear from these results that many allergic patients are more sensitive to injections of proteose and peptone than normal persons but that further investigation before one can decide on the nature of the reaction I am treating some of my patients suffering from these conditions with proteose and hope at a later date to publish a comparison of this method of treatment with other methods of desensitization —I am etc

NORMAN BURGESS MA MD MRCP
Cuffley Herts Dec 29th 1931

THE SOBERING UP RATE

SIR—Dr Knowles Bond writing on this subject in the *British Medical Journal* of December 12th 1931 speaks of the bewilderment of police courts and clerks of the court on hearing the prosecution's evidence of the sobering up rate in alcoholic cases This is consistent In view of the generally accepted opinion that both mental and physical symptoms of alcoholic poisoning succeed both physical and psychical causes something more than a measurement of the alcoholic concentration is surely demanded There is nothing more misleading than measurements and statistics and it is now obvious that Professor Widmark would regard consideration of measurement of alcohol elimination being used in this way

The empirical evidence of specialists on the value of coffee the necessity for self-control are not to be lightly set aside Few doctors will have not seen the sudden almost alarming transformation in an alcoholic case after an accident The alcoholic elimination may occur at a fixed

rate but it would be vain to ask for a fixed rate of change in the disappearance of intoxication Animal experimentation has been observed under constants, and the observation regarding the associated variations has very limited and but general importance Such an observation is a frail structure on which to build a pronouncement that the variation of elimination and disappearance of intoxication are constants and is certainly not borne out by the experience we have of intoxication in man

In the meantime your correspondent is at an entire disadvantage until some datum level of intoxication is obtainable for man otherwise the pretence of scientific accuracy will be as unconvincing to your medical readers as it apparently was to bench police counsel and clerk of the court —I am, etc

Liverpool Dec 18th 1931 T G M

CONSTIPATION AND RIGHT-SIDED PTOSIS

SIR —Dr J V Fiddian's paper in the *Journal* of December 12th 1931 contains so many valuable and true matters that he will assuredly grant me the privilege of pointing out where I believe he has gone astray

He attributes the haggard faces and emaciated frames of the toxaemic subjects of stasis to their addiction to cascara! True the purgation habit irrationally indulged aggravates the toxaemia but the taking of purgatives such as cascara is no part of the approved treatment of stasis Dr Fiddian is right when he states that 'probably all civilized humans' have some degree of rectal accumulation (dyschezia) 'It would be highly inconvenient otherwise, he comments and adds that even domestic animals are trained by man to put the rectal reflex out of action But the conclusion that nearly all stasis occurs either in the rectum or in the caecum is opposed to all my experience, now covering twenty five years I know quite well how the fallacy arose It was usual, in hospital practice for patients to be prepared for the x ray room as for an operation the intestines were washed out by a purge and an enema and the stomach was empty Under these conditions a bismuth meal travelled rapidly through the intestines to the rectum and remained there Almost every case thus became a case of dyschezia If however there were much pyloric spasm with a large, low lying stomach there would be a gastric residue of bismuth and after the first portions of bismuth had completed the rush to the rectum the remaining portions would reach the caecum and stay there the colon being now wearied by its efforts

When x ray observations are carried out under less artificial conditions the results are very different and show that in stasis the delay is spread over the entire large intestine and it is usual to find the transverse colon still well filled with bismuth after forty eight seventy two or more hours while the rectum may or may not be full also In stasis the caecum and ascending colon are bound to remain full actually they become widely distended and far more capacious than they should be This habitual overloading of the caecum and ascending colon causes them to become ptosed unless fibrous bands fasten them to the parietal wall An overloaded and mobile caecum may drop to the bottom of the pelvis the ascending colon may follow and compel the caecum to curl back behind it till its fundus may face directly upward This constitutes the periwinkle caecum which I described in the *Practitioner* of February 1929 One of the consequences of this extreme ptosis and retroversion of the caecum is to produce torsion of the end of the ileum and severe ileal stasis

This brings me to an astounding assertion by Dr Fiddian

> The terminal portion of the small intestine contains highly toxic material Nearly all the valuable products of digestion have been absorbed and the residue abounds in chemical and bacterial poisons This toxic fluid is normally dealt with in the caecum and ascending colon where it is detoxicated by dehydration

Unless I miss Dr Fiddian's argument he regards this as normal I am convinced the exact opposite is the case normally the contents of the lower ileal coils are sterile, or nearly so whereas the large intestine harbours microbes whose function in health is to aid digestion and assimilation by breaking down the cellulose walls of vegetable cells taken as food In health these microbes are 'friendly,' and produce no toxins other than can be dealt with by the healthy organism In stasis with toxaemia however these microbes cease to be friendly, they become highly virulent and especially so when they invade the stagnant contents of the lower ileum Other microbes (for example streptococci) foreign to the healthy bowel join the invading army and convert the lower ileal coils into a veritable cauldron from which poisons are poured into the system with deadly effect on every tissue of the body So far from being detoxicated by dehydration 'I should like to assure Dr Fiddian that soluble poisons are absorbed into the blood stream from the intestines quite as freely as the water in which they are dissolved

It is impossible within the limits of a letter, to go into every aspect of stasis, but I think I am justified in summarizing the present discussion as follows Where Dr Fiddian's conclusions are at variance with the facts as I see them the reason is to be found in a difference of opinion as to what is normal If it is normal for the human race to be constipated to the extent of limiting itself to the convenient standard of one bowel evacuation daily and if it is normal for the small intestine to be teeming with virulent microbes then the consequences which he and I and all of us are accustomed to see are normal also I still look forward however to a day when the medical profession will aspire to a higher and nobler destiny for mankind and will no longer contemplate with equanimity a race degraded by the results of toxaemia—such as rotten teeth rheumatism colitis appendicitis, gastric and duodenal ulcer and cancer of the digestive tract and its appendages —I am etc

London W 1 Dec 12th 1931 ALFRED C JORDAN

TREATMENT OF RHEUMATOID ARTHRITIS

SIR,—May I bring forward the following clinical observation? In 1928 I published my results of cases of unrelievable and incurable dry middle ear diseases treated with intravenous injections of colloidal iodine Some of these cases were accompanied by symptoms of muscular rheumatism and of osteo arthritis These symptoms in every case either ameliorated or disappeared I therefore suggested this treatment to my medical colleagues who confirmed my observations Collosol iodine is now used in Egypt on a large scale and I feel sure that if physicians in England give it a trial for rheumatic affections they will have no cause for disappointment For dosage I refer colleagues to an article in the *Journal of Laryngology and Otology* (1929 p 625) by Dr Dan McKenzie, under the heading of The symptomatic treatment of deafness and to a letter of mine published in the same journal (p 799 of the same volume) —I am, etc

Cairo Dec 12th 1931 HASSEN BEY SHAHEEN M Ch Cairo M R C S Eng

rate but it would be vain to ask for a fixed rate of change in the disappearance of intoxication Animal experimentation has been observed under constants and the observation regarding the associated variations has very limited and but general importance Such an observation is a frail structure on which to build a pronouncement that the variation of elimination and disappearance of intoxication are constants and is certainly not borne out by the experience we have of intoxication in man

In the meantime your correspondent is at an entire disadvantage until some datum level of intoxication is obtainable for man otherwise the pretence of scientific accuracy will be as unconvincing to your medical readers as it apparently was to bench, police counsel, and clerk of the court—I am etc

Liverpool Dec 18th 1931 T G M

CONSTIPATION AND RIGHT SIDED PTOSIS

SIR—Dr J V Fiddian's paper in the *Journal* of December 12th 1931 contains so many valuable and true matters that he will assuredly grant me the privilege of pointing out where I believe he has gone astray

He attributes the haggard faces and emaciated frames of the toxaemic subjects of stasis to their addiction to cascara! True the purgation habit irrationally indulged aggravates the toxaemia but the taking of purgatives such as cascara is no part of the approved treatment of stasis Dr Fiddian is right when he states that probably all civilized humans have some degree of rectal accumulation (dyschezia) It would be highly inconvenient otherwise' he comments and adds that even domestic animals are trained by man to put the rectal reflex out of action But the conclusion that nearly all stasis occurs either in the rectum or in the caecum is opposed to all my experience now covering twenty five years I know quite well how the fallacy arose It was usual in hospital practice for patients to be 'prepared for the x ray room as for an operation the intestines were washed out by a purge and an enema and the stomach was empty Under these conditions a bismuth meal travelled rapidly through the intestines to the rectum and remained there Almost every case thus became a case of dyschezia If however there were much pyloric spasm with a large low-lying stomach there would be a gastric residue of bismuth and after the first portions of bismuth had completed the rush to the rectum the remaining portions would reach the caecum and stay there the colon being now wearied by its efforts

When x ray observations are carried out under less artificial conditions the results are very different, and show that in stasis the delay is spread over the entire large intestine and it is usual to find the transverse colon still well filled with bismuth after forty eight seventy two or more hours while the rectum may or may not be full also In stasis the caecum and ascending colon are bound to remain full actually they become widely distended and far more capacious than they should be This habitual overloading of the caecum and ascending colon causes them to become ptosed unless fibrous bands fasten them to the parietal wall An overloaded and mobile caecum may drop to the bottom of the pelvis the ascending colon may follow and compel the caecum to curl back behind it till its fundus may face directly upward This constitutes the periwinkle caecum which I described in the *Practitioner* of February 1929 One of the consequences of this extreme ptosis and retroversion of the caecum is to produce torsion of the end of the ileum and severe ileal stasis

This brings me to an astounding assertion by Dr Fiddian

> The terminal portion of the small intestine contains highly toxic material Nearly all the valuable products of digestion have been absorbed and the residue abounds in chemical and bacterial poisons This toxic fluid is normally dealt with in the caecum and ascending colon where it is detoxicated by dehydration

Unless I miss Dr Fiddian's argument he regards this as normal I am convinced the exact opposite is the case normally the contents of the lower ileal coils are sterile, or nearly so whereas the large intestine harbours microbes whose function in health is to aid digestion and assimilation by breaking down the cellulose walls of vegetable cells taken as food In health these microbes are friendly and produce no toxins other than can be dealt with by the healthy organism In stasis with toxaemia however, these microbes cease to be friendly, they become highly virulent, and especially so when they invade the stagnant contents of the lower ileum Other microbes (for example streptococci) foreign to the healthy bowel join the invading army and convert the lower ileal coils into a veritable cauldron, from which poisons are poured into the system with deadly effect on every tissue of the body So far from being detoxicated by dehydration I should like to assure Dr Fiddian that soluble poisons are absorbed into the blood stream from the intestines quite as freely as the water in which they are dissolved

It is impossible, within the limits of a letter to go into every aspect of stasis but I think I am justified in summarizing the present discussion as follows Where Dr Fiddian's conclusions are at variance with the facts as I see them the reason is to be found in a difference of opinion as to what is normal If it is normal for the human race to be constipated to the extent of limiting itself to the 'convenient' standard of one bowel evacuation daily and if it is normal for the small intestine to be teeming with virulent microbes then the consequences which he and I and all of us are accustomed to see are normal also I still look forward however, to a day when the medical profession will aspire to a higher and nobler destiny for mankind and will no longer contemplate with equanimity a race degraded by the results of toxaemia—such as rotten teeth rheumatism colitis appendicitis gastric and duodenal ulcer, and cancer of the digestive tract and its appendages—I am etc

Cairo Dec 12th 1931 HASSAN BEY SHAHEEN, M Ch Cairo M R C S Eng

Dr Ellingworth dwells on the advance in hygienic education he makes no mention of such aspects as the general scarcity of soap the inadequate bathing facilities and the overcrowding of residential quarters He finds an excuse for slovenly beds in the hospitals in the fact that the lower classes in their homes never make their beds but the authorities surely should set an example to the people and not take their standards from the masses besides pre war hospitals would not have occasioned this comment Dr Ellingworth describes some model sanatoriums I trust he does not forget that for ten years before the world war the Imperial Maternity Home of Alexandra Feodorovna in St Petersburg, with 3 000 beds was everywhere regarded as one of the model hospitals of Europe

Dr Hilda Stoessiger says medicine has gained much from State control and adds that medical research has been encouraged But does she not realize that under the old regime medicine was one of several branches of science in which Russia was doing brilliant research work? In some fields such as histology Russians were pre eminent and pre war Russian histologists to this day are instructing English French and American students The old time Russian general practitioner maintained a very high average standard in devotion to his profession and in the practical handling of diagnosis and treatment Russian medical students and doctors were imbued with an idealism an enthusiasm a spirit of sacrifice and service which would I am sure have impressed Drs Ellingworth and Stoessiger profoundly One striking feature of pre war medicine in Russia was the complete absence of the mercenary spirit it may interest your readers to know that the universal practice in Russia was for patients to pay what they chose to pay slipping the fee into the hand of the doctor as the latter left the house a doctor who would haggle over his fee was guilty of unprofessional conduct and would lose prestige

Neither Dr Ellingworth nor Dr Stoessiger discusses the standards of present day medical education in Russia where hardly literate proletarian peasants are being sent forth after a two year course to maintain the health of their communities armed perhaps with glorious enthusiasm but with less knowledge of medicine than is possessed in England by a pharmacist or an experienced nurse The truth is that the Revolution has gone far toward stamping out a brilliantly promising school of research workers non mercenary specialists and competent devoted general practitioners The hard won prosaic accomplishments of a noble medical tradition have been replaced by a dualism of infantile hopes and enthusiasm (sometimes embodied in show exhibits) on the one hand and an appalling chaos in actual achievement on the other —I am etc

THE LAW AND ABORTION

SIR —In the *Journal* of December 19th 1931 (p 1143) Dr L A Parry states that abortion was punishable at Common Law *Would he state* where an indictment for abortion can be found or a report of a trial in a common law court? I do not mean an indictment for murder or manslaughter or grievous bodily harm but for abortion alone without any ill consequences The Common Law maxim is *Volenti non fit injuria* Termes de la ley has no mention of it and I have searched in vain Coke's *Institutes* and *Coke upon Littleton* I have always understood that this was an offence triable only in the Ecclesiastical Courts The contempt in which these courts were held in the time of Chaucer is known to all who have read the *Canterbury Tales* The Friar's quarrel with the Sumpnour and the Friar's tale of how the Devil carried away another Sumpnour show an utter indifference not merely to the methods of obtaining evidence but to common honesty As for the reply of the Sumpnour I fear you could not print it —I am etc,

GEORGE JONES M B,

Obituary

WILLIAM LOUDON REID, M D F R F P S

Consulting Gynaecologist Western Infirmary Glasgow

The death took place on December 17th 1931 at his home in Cumbernauld in Lanarkshire of Dr William Loudon Reid in his day an obstetrician and gynaecologist of wide repute in Scotland, and a former president of the Royal Faculty of Physicians and Surgeons of Glasgow Dr Reid who was in his eighty seventh year retired from active practice about twenty years ago

He was born at Motherwell and from St John's Grammar School Hamilton went to study medicine at Glasgow University graduating M B C M in 1866 and taking the M D in 1869 It was a stimulating experience to be a medical student in the Glasgow of the sixties when Lister then Regius Professor of Surgery at the University was introducing and perfecting the antiseptic treatment of wounds Reid had the good fortune to gain two gold medals in Lister's surgery classes and to act for a time as Lister's dresser He started in general practice in Central Glasgow but soon began to specialize in obstetrics and gynaecology and his reputation in this branch of medicine quickly spread beyond the boundaries of the city In 1877 he was appointed outdoor physician-accoucheur to Glasgow Maternity Hospital and afterwards physician for diseases of women to the Western Infirmary This was followed by his appointment in 1883 as physician and lecturer on clinical obstetrics at the Maternity Hospital and six years later as professor of midwifery and diseases of women and children at the Anderson College of Medicine Glasgow In 1892 he became consulting physician to the Maternity Hospital and in 1894 physician and lecturer in clinical gynaecology at the Western Infirmary He had been made a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow in 1877 and was afterwards examiner in midwifery and diseases of women for that corporation and its president for a term His long association with the Faculty was crowned last year when with three other distinguished men—Professor Robert Muir of Glasgow, Professor Laurence Waddell of Calcutta and Professor Wenckebach of Vienna—he received the Honorary Fellowship In bestowing this mark of recognition the president Dr John F Fergus said that Dr Reid now in a venerable but serenely happy and even sprightly old age was a pioneer in the scientific development of obstetrics and gynaecology one who by his teaching and example had done much to raise the school of obstetrics and gynaecology in Glasgow to the high position which it now occupies By his skill and by the simplicity and integrity of his character he gained the confidence of a large circle of patients who regarded him as a trusted and able adviser and also of medical men who found in him a helpful and loyal colleague

In an earlier generation of medical society life in Scotland Dr Reid was a conspicuous figure He had filled the chair of the Glasgow Obstetrical and Gynaecological Society and of the Medico Chirurgical Society of Glasgow and was an honorary Fellow of the Obstetrical Society of Edinburgh He was a member of the Lanarkshire Division of the British Medical Association He had an inventive turn of mind and introduced new forms

UNIVERSITY OF LONDON

Dr O L V de Wesselow F R C P has been appointed as from December 1st 1931 to the University Chair of Medicine tenable at St Thomas's Hospital Medical School

UNIVERSITY COLLEGE

A course of six lectures on the physiology of reproduction will be given by Dr A S Parkes on Fridays January 15th 22nd and 29th and February 5th 12th and 19th at 5 p m Mr G P Wells will give a course of ten lectures on comparative physiology on Fridays January 15th 22nd and 29th February 5th 12th 19th and 26th and March 4th 11th and 18th at 5 p m Admission free

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The next series of eight lectures and demonstrations on tropical hygiene which are intended for men and women outside the medical profession proceeding to the Tropics will be given by Lieut Colonel G E F Stammers from January 11th to 20th These courses of instruction in addition to providing simple rules for guidance in regard to personal hygiene and preparation for life in the Tropics will also embrace a short account of some of the more common diseases with advice in regard to measures of protection and self treatment The synopsis and other particulars can be obtained from the secretary London School of Hygiene and Tropical Medicine Keppel Street Gower Street W C 1

UNIVERSITY OF DURHAM

At the convocation held on December 19th 1931 the following degrees and diplomas were conferred

Medical News

At a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine to be held on Thursday January 7th at 5 p m Dr W Schulemann of Elberfeld, Germany will read a paper on synthetic anti malarial preparations He will discuss the various steps which led to the synthesis and discovery of plasmoquine and give a brief account of its use in tropical medicine

Dr F E Fremantle M P will give an address on the debt of the Empire to British medical research at a meeting of the Royal Empire Society, to be held at the Hotel Victoria London on Tuesday January 19th at 8 30 p m with Sir William Willcox M D in the chair Applications for tickets which are free should be addressed to the secretary of the Royal Empire Society Northumberland Avenue W C 2 A dinner will precede the meeting at 7 o clock and those wishing to be present at that also should forward 10s 6d in payment of each ticket required

At the opening of the second winter session of the Hampstead General and North West London Hospital Post Graduate School on January 6th at 4 p m Lord Riddell will deliver an address on The ethics of abortion sterilization and birth control

The next series of free weekly lectures at St Peter's Hospital Henrietta Street W C 2 will begin on Wednesday January 20th, at 3 p m when Mr Swift Joly will discuss the examination of urological patients The course will end on Wednesday March 9th when Dr Cuthbert Dukes will lecture on tumours of the upper urinary tract

The first of the twentieth series of Chadwick Lectures will be given by Dr J D Rolleston on February 18th at the Medical Society of London on Benjamin Ward Richardson his life and work Information about these lectures may be obtained from the secretary, Mrs Aubrey Richardson at the offices of the Chadwick Trust, 204 Abbey House Westminster S W 1

Intestinal Flatulence

Dr MARY G CARDWELL (Oldham) writes If 'Puzzled' advises the following treatment his patient will find the attacks of flatulence much improved Reduce carbohydrate intake very strictly especially with regard to bread Prescribe colonic lavage with saline or sulphur lotion twice weekly for four weeks and thereafter once a fortnight for at least three months Kaylene oil by the mouth three times daily should be taken over an extended period

Dr J R WILLIAMS (Penmaenmawr) writes I suggest that Puzzled (December 19th 1931 p 1163) should try alocol tablets (colloidal aluminium hydroxide) two or even three to be taken about half an hour before and the same shortly after each meal

Depopulation

Dr B DUNLOP (London S W) writes In the notes from your correspondent in France (December 19th 1931 p 1153) it is stated that a decline of its population would be a great danger This is sad because a reduction of its numbers seems necessary if the standard of living is to be further raised Must the French postpone this and endure their low wages and long hours until their neighbours have got rid of pressure of population?

Income Tax

Casual Earnings

E S holds a hospital appointment and from time to time earns casual fees as locumtenent and for assisting at operations Are such casual earnings assessable and if so on what basis?

*** They are assessable The appropriate basis is normally the amount earned in the year preceding the year of assessment but for the year when such work was commenced the basis would be the current year's earnings If no record has been kept of the sums earned the only course open to E S is to make an estimated return using such material—bank pass book diary etc—as he may have

Residence—Professional Use

A O in taking over a practice had to take a house which was too big for his requirements Of the twenty rooms the house contains nine are used for the practice alone and five for private use alone A O claims to be allowed two thirds but the inspector of taxes declines to allow more than one half of the rent rates etc

*** It would seem that the inspector of taxes may be looking at this case as if nine rooms are used professionally and eleven are used or are available for use privately If so we think that he overlooks a rather important factor—that is that the six unused rooms have probably no real rental value at all the house being of a type unsuitable for modern requirements and one by which a prospective tenant would be repelled rather than attracted by the six surplus rooms On that basis the rent to be divided between practice and domestic use is for the fourteen rooms actually in use and unless the professional rooms are inferior in situation etc to the others—the reverse is probably the case—our correspondent's claim to two thirds seems justified

LETTERS NOTES ETC

A Warning

Dr F M R WALSHE writes It has come to my knowledge that the managing director of a limited company is communicating with members of the profession in connexion with a scheme for appointing medical experts and referees in regard to a life insurance business which his company is trying to operate and in one instance which is known to me he has stated that he had been recommended by me and that I am one of his company's medical experts This is entirely untrue and is emphatically denied by me In the circumstances I consider it is my duty to warn members of the profession that I have never given authority for my name to be used by this gentleman under any circumstances whatever and to make full inquiry before entertaining any proposal he may make

Canine Tooth Erupting Externally

Dr LEWIS S ROBERTSON medical superintendent of Pretoria Hospital sends the photograph of a native boy reproduced in this column It will be seen that the left upper canine tooth has erupted near the antrum perpendicular to the jaw and has penetrated the upper lip J F Colyer (*Dental Surgery and Pathology* 1923) says that the canine is totally displaced from the arch more frequently than any other tooth but not many cases similar to Dr Robertson's case have been recorded The following are taken from *Anomalies and Curiosities of Medicine* by Gould and Pyle (1897) Roy in 1883 described the eruption of a canine in the nose of a Hindoo aged 14 and Hill in 1883 described a similar case in a girl with congenital syphilis Branch in 1884 reported a case of a negro boy with two large teeth in the nose At a meeting of the Medical Society of Christiania in 1895 a tooth was shown which had been removed from a woman aged 53 it resembled a milk canine and was situated in a small depression at the junction of the floor and external wall of the nasal cavity 22 mm from the external nares

Association of Bio Physical Assistants

Messrs E FORT and R J DEACON (London W 1) write Notices have recently appeared in some professional journals (but not the *British Medical Journal*) regarding a movement to form an association for bio physical assistants in which our names appear as members of the provisional organizing committee Our names are followed in the notices by the respective designation—member of the council of the Chartered Society of Massage and Medical Gymnastics and member of the General Purposes Committee of the Chartered Society of Massage and Medical Gymnastics We are asked by the secretary of the Chartered Society to make clear that this does not imply that we represent the Chartered Society in an official capacity on this committee Our purpose in adding the above mentioned designation was to make clear that the new movement is supported by persons of standing in the profession who even though closely associated with the Chartered Society realize that the new Association of Bio Physical Assistants is essential Our purpose was also to show that there is no possible antagonism between the new association and the Chartered Society and therefore that all Chartered Society members who are bio physical assistants should also join the new association

Replies to Drug Advertisements

The head of a well known firm of manufacturing chemists asks leave to suggest that medical men when writing to drug manufacturers etc in response to advertisements should put their qualifications after their names or in some other way convey that they are members of the medical profession This is done he adds a good deal in other countries We have the greatest difficulty sometimes in determining whether people who write to us are medical men at all Naturally we do not wish to overstep the mark by writing to members of the public as if they were doctors The suggestion seems most reasonable

Vacancies

Notifications of offices vacant in universities medical colleges and of vacant resident and other appointments at hospitals will be found at pages 46 47 48 49 52 and 53 of our advertisement columns and advertisements as to partnerships assistantships and locumtenencies at pages 50 and 51

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 7

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 The Heart in Scarlet Fever

C. SNOOKHOFF and L. VAN TARIN (*Amer. Journ. Dis. Child.* September 1931, p. 554) record observations with the Cambridge portable electrocardiograph on 50 children aged from 5 to 13 suffering from scarlet fever, which was mild in 41 cases, moderate in 8, and severe in one. The results were as follows. The cardiac rate did not differ from that of normal children in the same age group. In children with fever the increase in rate was commensurate with the increase in temperature. A relative bradycardia, beginning in the second week and returning to normal at the end of the third week, was found in 25 per cent. Sinus arrhythmia occurred just as frequently as in normal children. No prolongations of the P–R interval were observed, and only minor changes in the T or R–T waves in 10 per cent., the changes returned to normal before the patient left hospital. An abnormal axial deviation during the course of the illness was noticed in 16 per cent., but with one exception the patient became normal again before discharge. These observations differ from those described in rheumatic fever in the comparative infrequency of electrocardiographic evidence of myocardial involvement in there being no tendency for abnormalities to persist, and in the absence of prolongation of the P–R interval.

2 Chronic Bronchitis due to Persistent Nasopharyngitis

W. W. PRIDDLE (*Canad. Med. Assoc. Journ.* October 1931, p. 441) reports three cases in which chronic bronchial infection was traced to chronic nasopharyngitis which had followed an acute infection such as influenza or whooping-cough. These occurred in a group of cases of the same kind in which no lesions were present in the accessory nasal sinuses or tonsils. The surface of the nasopharynx appeared swollen and congested, and there was a purulent or muco-purulent exudate on the mucous membrane. The bronchial signs indicated the presence of an intermittent infection, so 5 to 10 per cent. aqueous solution with 2 drachms to the ounce of 3 per cent. ephedrine hydrochloride was introduced into the nostrils by the dropper method, the head being well tilted back over the edge of the bed. When the mixture reached the pharynx the patient sat up and expectorated the excess. For the bronchial condition a combination of ephedrine, creosote, and a stimulating expectorant was employed early in the course of treatment, and the response to the two procedures was swift and satisfactory. Pridale is satisfied that a certain number of cases of chronic non-tuberculous disease are brought about by such a nasopharyngitis, and he has found that conservative medical treatment of the etiological focus as well as of the bronchial condition has produced uniformly good results.

3 Pernicious Anaemia complicated by Miliary Tuberculosis

W. FREEMAN (*Journ. Amer. Med. Assoc.* October 3rd, 1931, p. 996), who records a case in which tuberculosis occurred during the treatment of a negress aged 65 for pernicious anaemia, states that only nine cases of such an association have been recorded in the literature since 1898. Acute miliary tuberculosis is even less common as a complication. The severity of the pernicious anaemia in Freeman's case was demonstrated by the haematological examination, the weakness, loss of appetite, and the absence at first of any signs of tuberculosis. Liver therapy was started, and slow but definite improvement resulted as far as the blood condition was concerned. The onset of tuberculosis was at first insidious, but when the acute miliary process began the patient became rapidly worse, and death ensued. The original tuberculous focus was found in the peribronchial lymphatic glands, which showed complete destruction, a dense fibrous wall encapsulating caseous material. The miliary tubercles which studded the lungs, liver, spleen, and peritoneum were histologically typical, there being a definite absence of fibroblastic proliferation, lymphocytic infiltration, and giant cells. Caseation necrosis, infiltration by monocytes, and many acid-fast bacilli were demonstrated in both lungs. The usual post-mortem appearances of pernicious anaemia were present, with the exception of glossitis, subcutaneous and submucous haemorrhages, fatty degeneration of the myocardium, and atrophy of the gastric mucosa, while atypical conditions of the spleen, liver, and femoral bone marrow were noted. The author briefly reviews the literature in this connexion, and mentions that as regards the tuberculous symptoms there was no high evening temperature, herpes, or leucocytosis, which would be expected in the miliary type.

4 Bronchitis in Hypertension

According to A. DENIS and A. REID (*Arch. Int. Med.* September 15th, 1931, p. 281) chronic bronchitis frequently develops in hypertensive subjects. The chief functional symptom is a characteristic cough, occurring during the day or at night or only on waking. The expectoration, which is the main physical sign, may be scanty or very abundant, usually clear and serous, it may become viscous or even muco-purulent. Coarse rales are always heard sometimes over one base, sometimes at the apex; in the latter case tuberculosis may be erroneously suspected. In some cases the bronchitis is afebrile with subsistent rales over both lungs. The chief characters of this affection are its persistence, its tenacity, and its relation to vascular rather than expectorant medication. It may be an early complication of hypertension, but itself is most intense in the second or organic phase. It is noted in moderate as well as very advanced hypertensives. The bronchitis is frequently more marked when albuminuria appears; the two conditions then evolve concurrently. In a more advanced stage of hypertension bronchitis may be a sign of commencing cardiac insufficiency. This affection is probably due to troubles in the small circulation caused by the general hypertension. This point is discussed, as is also the frequency of symptoms of abortive pulmonary oedema. Treatment, both symptomatic and general, depends on the type of case. Cases with slight cardiac insufficiency should be given digitalis; iodides or various forms of specific treatment are indicated when there is a local cause.

5 Acrodynia

According to M. PERIC and H. JANICOT (*Presse Méd.* November 7th, 1931, p. 1890) loss of muscle tone is observed in the majority of cases of acrodynia; clonic contractions occur occasionally. The left upper eyelid and left halves of the upper and lower lips were thus affected in a child aged 7, while a 5-year-old child had marked clonic contractions in the right lower limb. Clonus has also been observed in the adult, and it is significant that it is generally a manifestation of encephalitis. Enlarged glands in the occipital, carotid, and inguinal regions, to about the size of a walnut, were noted in an infant of 6 months; they regressed with the other signs of the disease. Acrodynia is ushered in with a pyrexial period, but during the greater part of its course the temperature is normal. The cerebro-spinal fluid is generally not involved, but in certain cases cells and albumin are present. There may be a slight increase in the glucose; hyperglycaemia is definitely unusual. In attenuated forms the erythema may be vague or transient; it may be confined to the palmar surface of the fingers or even the tips only, without the palm or the dorsum of the fingers being

involved Even this slight degree of erythema is associated with intense pain not merely in the hypogastric region but in all the fingers and toes with loss of weight and of muscle tone and persistent tachycardia As regards the incidence of acrodynia during certain nerve diseases it has been observed to occur in the course of acute anterior poliomyelitis and acute epidemic encephalitis while acute encephalitis has developed during the course of acrodynia The pathological condition generally clears up in six to twelve months, nine necropsies are described in the literature Paterson and Greenfield have noted the disappearance of the myelin sheath in the peripheral nerve bundles, with a chronic inflammation of the medulla and the sensory nerves Other authors have described lesions in the basal and bulbar nuclei in the diencephalon in the endocrine organs and in the sympathetic system There is an upset of the vago sympathetic equilibrium hypertony of the vagus is evident from the apathy depression fatigue excessive sweating and salivation coldness of the extremities and urticaria while insomnia tremors tachycardia and arterial hypertension are due to hypertony of the sympathetic system From clinical analogy the disease would seem to be due to a neurotropic virus and there may be some association between acrodynia epidemic encephalitis and poliomyelitis Crookshank considers these three conditions to be due to the same cause—namely influenza involving the nervous system

Surgery

6 Operative Treatment of Gall stones

A KROGIUS (*Finska Lakaresallskapets Handlingar* September 1931 p 681) summarizes his own experience and that of others with regard to the surgery of gall stones While it would be deplorable if the operative treatment of gall stones were to become as popular a procedure as has appendicectomy in many quarters it is by earlier operative intervention that improvements in this field are to be effected The mortality from operations at every stage of the disease ranges from 4 6 to 10 6 per cent in the statistics of different surgeons whereas the mortality from early operations during the acute stage ranges only from 0 to 7 5 per cent the average being 4 per cent even though most of the statistics concerned include a certain proportion of neglected cases The operation mortality for uncomplicated cholecystectomy in a free interval is only 1 per cent and this operation in the hands of an experienced surgeon can therefore no longer be regarded as dangerous But the author does not recommend as a rule deferring an operation to a free interval On the contrary he believes that the path to better results lies in having recourse more frequently to operative intervention in the acute as well as in the early stage of the disease He supports this opinion with many pages of statistics and the experience of other surgeons

7 Total Colectomy

F W RANKIN (*Annals of Surgery* October 1931 p 676) reports six cases of total or subtotal removal of the colon Subtotal colectomy is the term used for the removal of the colon down to the juncture of the sigmoid with the rectum while colectomy consists of the complete exairesis of the colon sigmoid and rectum The two indications for total colectomy are a definite primary lesion such as polyposis and a secondary lesion such as complicated chronic ulcerative colitis with sequels Polyps in the colon may be of the type which is a true neoplasm or the result of an inflammatory reaction The neoplastic or congenital type may be present either as one or two discrete tumours or as discrete tumours which involve the entire mucosal surface of the bowel from the anal canal to the ileo caecal coil They occur usually in families and are very liable to undergo malignant change The diagnosis of congenital polyposis is made by digital or proctoscopic examination and may be confirmed by *x* rays Three cases of this type are reported, in each of which a three stage operation of ileostomy was performed, after partial colectomy the rectal stump was turned in and placed retroperitoneally and a posterior resection of the rectal stump was undertaken The result in two cases was good but the third patient died eleven months after the final operation Three further cases of total colectomy following chronic ulcerative colitis are reported These patients had all been suffering for some time from the effects of absorption caused by a useless infected foul large bowel containing pus with multiple arthritic lesions or fistulas It has been proved that chronic irritation of long duration initiates carcinomatous changes and therefore progressive ulcerative colitis is a factor in malignancy In all three of the cases reported a diffuse formation of polyps was found covering the entire intraluminary mucosa of the bowel In each instance total colectomy following partial colectomy was carried out with excellent results the patients making good recoveries The advantages of graded removal of the large bowel and rectum are emphasized as is also the necessity for early operation before malignant changes have ensued

8 Primary Adenocarcinoma of the Gall bladder

A CIOFFI (*Il Policlinico* Sez Chir October 15th 1931 p 541) who records an illustrative case states that primary cancer of the gall bladder was described at the Paris Anatomical Society in 1836 by Durant-Fardel who reported three examples The first important surgical study of the subject was made in 1894 by Heddaus of Czerny's Surgical Clinic Simple tumours of the gall-bladder—such as lipoma, fibroma and fibro papilloma, as well as primary sarcoma—are rare carcinoma being by far the most frequent occurring according to different observers in from 5 to 7 per cent of all necropsies It arises either in the gall bladder or in the bile ducts It is a disease of maturity being rare under 30 and over 80 It is four times more common in females than in males Its frequent association with cholelithiasis had been noted since 1849 When the tumour is circumscribed its most frequent starting point is the fundus of the gall bladder, then the walls and lastly the neck In many cases however, the whole organ is found to be involved so that the starting point is difficult to determine Histologically the growth may be a single carcinoma a cylindrical celled carcinoma or an adenocarcinoma with or without colloid degeneration Cioffi's case occurred in a woman aged 46 in whom the gall bladder tumour was found on laparotomy to be accompanied by metastases in the liver and stomach so that no further operation was performed No calculi were found Histological examination of a portion of the growth showed that it was an adenocarcinoma The issue of the case is not recorded

9 Spiral Deformity of the Oesophagus

B HEYERS (*Deut med Woch* November 6th 1931 p 1897) describes a case illustrative of the importance of radiographical examination in cases of oesophageal obstruction It has been proved that in a large number of cases the oesophagus is rotated throughout its entire length to the extent of 180 degrees and that slight stenosis is present the condition here recorded does not appear to have been noted hitherto A powerfully built man, aged 53 was admitted for sudden haematemesis Eighteen years previously he had contracted syphilis and was treated by inunctions He smoked and drank heavily In 1927 he had coffee ground vomiting but a skiagram revealed no abnormality, and he remained well until the day of admission to hospital Physical examination showed some chronic bronchitis and the occasional presence of extrasystoles He had no abdominal symptoms The left pupil was larger than the right and reacted better to light both reacted well for convergence The patellar and Achilles tendon reflexes were well There were traces of blood in the faeces The blood Wassermann reaction was negative After four weeks rest there was no recurrence of the pain Skiagrams

showed slight dilatation of the upper half of the oesophagus with a spiral constriction of the lower half peristaltic movements were deficient although the oesophagus became elongated on deep inspiration There was no evidence of cardiospasm of organic stenosis of the lower oesophagus or of the cardia The stomach and duodenum appeared to be normal In view of the possible presence of oesophageal varices from hepatic cirrhosis oesophagoscopy was not attempted The patient was discharged and ten weeks later he was in good health although the skiagraphic appearance was unchanged Heyers suggests that the condition may be due to oesophageal ulceration possibly syphilitic or to kinking elongation or dragging of the oesophagus or possibly to a defect of innervation of the oesophageal wall

10 Treatment of Carcinoma of the Urethra

F v Mikulicz-Radecki (*Zentralbl f Gynäk* October 3rd 1931 p 2922) publishes details of fourteen cases of carcinoma of the urethra treated at the Berlin Universitäts Frauenklinik during the past eighteen years The treatment recommended is excision of the inguinal and femoral glands on both sides together with radium therapy (a maximum of 2 000 mg hours) of the tumour Its results although disappointing are described as being less unfavourable than those of partial or radical excision In the case of more elderly patients treated by radium survivals of nine five and three years were noted of four patients recently treated by the combined method three have survived for three years without recurrence and with continence of urine

Therapeutics

11 Insulin Treatment of Cutaneous Carcinoma

S F Gomes da Costa (*Presse Méd* October 21st 1931 p 1541) reviews the literature dealing with the relations between the metabolism of cancers and carbohydrates Various workers have shown that cancerous tissue utilizes the carbohydrates often sixty-six times as much as do normal tissues and that this activity is due to glycolysis and not to oxidation Insulin has a similar action on these substances and its effects on cancer have been studied by numerous investigators The results have been contradictory but the insulin was always administered internally Da Costa believing that local application of insulin would cause a carbohydrate deficiency and thus create conditions unfavourable to the development of cancer has tried this method in twelve cases of cutaneous carcinoma three of which are here recorded as being illustrative of the advantageous results obtained The insulin always produced even in *recurrences* a rapid cicatrization of the cancer area commencing at the periphery in some cases this occurred in 3 to 4 weeks Microscopically a *marked regression* of the growth was revealed The technique of the treatment was as follows Insulin was dropped twice daily on the neoplasm so that the growth was *completely bathed* by it A sterile dressing moistened with a few drops of the solution was then applied

12 Stramonium in Parkinsonism

O J Menard and L M Hurxthal (*New England Journ Med* October 15th 1931 p 759) report cases illustrating their contention that stramonium datura in adequate dosage is a helpful drug in attempting to alleviate some of the distressing symptoms in Parkinson's disease or in post encephalitic Parkinsonism They think it should be tried in all cases being more effective than hyoscine preparations Atropine was employed in one of their cases but had to be discontinued in a few days owing to visual disturbances The authors state that in a few instances the mentally retarded bed ridden and helpless patients became active, alert and able to look after themselves other patients less severely afflicted attained variable degrees of improvement They used the powdered leaves only first in capsules and later in pill form the usually effective dose being 5 to 7 grains each day At first doses of 2 5 grains were given three times daily increases or reductions being made subsequently as thought fit It is recommended that the dosage should be raised to the maximum before the treatment is abandoned as unsatisfactory Some of the authors patients had been taking 15 grains each day and in one case the daily dose was 22 5 grains Dryness of the mouth and visual disturbance may occur at first but is usually transient and no other harmful effects have been noted The treatment almost invariably relieves the muscular rigidity and mental retardation often most strikingly The pill rolling type of tremor lessens and sometimes (though rarely) disappears Excessive salivation is always stopped but the marked faces and stare are rarely benefited Of 22 patients reported 6 experienced marked improvement 6 improved moderately 6 received slight benefit and 4 were unimproved

13 Therapeutics of Scleroderma

Michaëlis (*Bruxelles-Medical* October 25th 1931 p 1502) describes a method of treatment used by Sellei of Budapest who gives pastilles of pancreas (pancrine) and also the raw organ in soup reinforcing this with a diet poor in fats and with the administration of preparations of the mucous membrane of the stomach and duodenum Sellei claims to have obtained great benefit in the general condition without however influencing the accompanying sclerodactyly facial mask and Raynaud syndrome he believes that this partial failure shows that scleroderma and the Raynaud syndrome depend on a different pathology Michaëlis recalls his own publication in 1929 of a case of scleroderma successfully treated by massive doses of insulin not specially purified the course consisted of over 4 000 units in doses of from 60 to 120 units in this case the facies sclerodactyly and Raynaud syndrome were also cleared up Since insulin is not utilized by diabetics when given by the mouth Michaëlis concludes that Sellei's success is not due to any insulin content of the pancreatic substance moreover Sellei has investigated the sugar tolerance and diastatic indices in several cases where his treatment succeeded and found them to be normal Michaëlis doubts whether his method and that of Sellei depend on direct stimulation of the unstriated muscle of the skin and blood vessels by a number of different *hormones* In view of the difficulty experienced in getting *patients to tolerate* high doses of insulin he suggests that a combination of his own method with the pancreatic therapy of Sellei might prove better than either method alone Finally he considers that the occasional presence of achylia in cases of scleroderma gives some support to Sellei's use of gastric and duodenal extracts in addition

14 Intramuscular Injections of Quinine in Pneumonia

H Roos (*Finska Läkaresällskapets Handlingar* October 1931 p 778) traces the evolution of the treatment of pneumonia with injections of quinine since 1899 The favourable experiences of earlier workers are confirmed by the author who in December 1927 and throughout 1928 treated every other case of pneumonia admitted to his hospital with injections of quinine letting the alternate cases serve as controls The solution injected consisted of 2 parts of quinine hydrochloride 1 part of urethane and 20 parts of distilled water The usual dose was 5 c cm injected on the first second fourth and sixth days of the course of treatment Since the quinine was liable to form a precipitate at room temperature it was gently warmed before injection Among the 105 patients thus treated there were 9 deaths whereas among the 84 controls there were as many as 13 deaths The comparison between the two groups of cases was not however quite fair since only 15 per cent of the quinine-treated patients were over the age of 50 whereas this was the case with nearly 30 per cent of the controls The cases were accordingly re classified so that *only* the patients between the ages of 15 and 50 in both groups

and only those in the quinine treated group whose treatment began before the fifth day of the disease were included There were 56 quinine treated patients in this group with an average age of 28, and among them there were only two deaths The average age of the 59 controls was 30 and there were 7 deaths among them The clinical course of the cases in the two groups showed this remarkable difference—that while the temperature usually fell by lysis in the quinine treated cases, that of the controls most frequently fell by crisis The average duration of the fever was, however approximately the same Complications also were as common among the quinine treated patients as among the controls, and no striking improvement in the general condition after the injections was observed The author considers that his experience confirms the favourable reports of earlier workers on this treatment

15 Intestinal Action of Camphor

H BUSQUET and A JAUROU (*Bull Soc de Ther* October, 1931 p 259) state that the action of camphor on intestinal pain was first noted by Nicolas Alexandre in 1750 in his botanical dictionary and its constipating effects were described by Vitet in 1803 in his *Materia Medica* Graffenhauer in a monograph on camphor published in the same year emphasized its sedative action in colic Millot advocated its use in acute colitis in 1837 Since then however little attention was paid to the sedative action of camphor on the intestine until Busquet read a paper on the subject before the Société de Biologie in June 1930 In his recent Paris thesis Jaurou recorded 14 cases of diarrhoea due to different causes and usually attended by colic and fever which he had treated by camphor The use of this drug produced within the first few hours a diminution in the number of the stools a considerable relief of the colic and a fall of the temperature to normal The daily dose of camphor should not exceed 0 25 gram It is best prescribed in a watery solution with an appropriate syrup to correct the disagreeable taste

Neurology and Psychology

16 Diet and Degeneration of the Spinal Cord

E MELLANBY (*Brain* September 1931 p 247) reports a series of investigations showing that when diets containing a large amount of cereal (other than yellow maize) deficient in vitamin A or carotene are eaten by young puppies degenerative changes in the spinal cord in the form of demyelination of the nerve fibres can generally be observed if Marchi's method of staining is employed The addition to the diet of ergot or rye germ hastens and intensifies these changes which are prevented on the other hand by the presence of any rich source of vitamin A or of carotene even though ergot is being eaten Spinal cord degeneration of this type does not seem to develop until the reserves of vitamin A in the liver are used up The author comments on the possible bearing of these results on certain clinical conditions Demyelination of the cord fibres is such a characteristic change in pernicious anaemia that it may possibly be associated with failure of the liver to store vitamin A or with prevention of this substance from exerting its normal function on the central nervous system Subacute systemic lesions of the cord are also found in Addison's disease and cancer cachexia carotene and vitamin A might be remarked prevent or influence these changes Mellanby suggests that further investigation might bring to light some similar etiology in the degenerative cord changes in tabes dorsalis and general paralysis while the remissions in disseminated sclerosis indicate the possibility of there being some such preventive mechanism of the nervous system operating as is exerted by carotene and vitamin A Furthermore the partial deficiency of these preventive substances may be concerned with some of the slighter but more common abnormalities of the nervous system The author thinks that the beneficial effect of the malarial treatment of general paralysis might possibly be due to the liberation of large quantities of vitamin A and other preventive factors from the livers of patients infected with the malarial parasite, and that it might be worth while as a preliminary measure to place such patients on diets rich in this substance and in cod liver oil with a view to rendering the subsequent malarial therapy more regular and satisfactory in its effects

17 Focal Infections in Certain Psychoses

G GIBIER RAMBAUD (*Presse Med* October 10th, 1931, p 1479) records four cases of dementia praecox in all of which dental trouble was present amelioration, if not cure, followed extraction of the diseased teeth and vaccine treatment The vaccine was made from an anaerobic neurotropic *Streptococcus viridans* isolated from the teeth and in two cases from the tonsils as well Intestinal disinfection also was instituted at the onset of treatment, and continued during its course In these cases the streptococcus acting through its toxin on the nerve cells or neurinis was apparently the cause of dementia While admitting that the cases are too few on which to base dogmatic conclusions the author draws attention to the fact that acute infectious diseases may be accompanied by mental troubles and to the important part played by streptococci in acute rheumatism and endocarditis He believes that at the onset of all psychoses, infectious foci (such as those in the nasopharynx, tonsils teeth prostate and cervix uteri) should be looked for, and if found appropriately treated

18 The Position in the Family of Mental Defectives

L D TURNER and L S PENROSE (*Journ of Mental Science* July 1931 p 512) attempt to answer the question whether the place in the family occupied by a mentally defective child has any influence as a cause of the mental defect A questionary was issued and 1 455 replies were received but on the whole the results were disappointing owing to the failure to eliminate certain sources of error Despite these drawbacks the authors believe that the evidence obtained although weak points to the following conclusions In low grades of amentia (idiots) the first born child is somewhat more frequently affected than the other members of the fraternity In high grades of amentia the defectives are more frequently found among the later-born members Certain special groups of cases have their own peculiar distribution in the family mongols tend to come last and cases with a history of difficult labour are likely to come early The data give no support to Goddard's hypothesis that mental deficiency is due to a single recessive gene substitution

19 Heredity in Schizophrenia

M BLEULER (*Journ of Nerv and Ment Dis* October, 1931, p 393) records a study of 100 schizophrenic patients with special reference to the family, no fewer than 2 634 persons being included in the investigation Since the biological unity of the group of schizophrenias is not probable an attempt was made to discover whether familial influences were of equal importance in different forms of this condition Bleuler submits the following generalizations as conjectures Among schizophrenics without hereditary evidence one group is sharply distinguished clinically, the patients have severe dementia but are capable of a certain affective rapport (such as idiots have) their bearing and expression are apathetic Their illness began early ran a quick progressive course and showed no substantial remissions Physically they were obese dysplastics, before the psychosis manifested itself, they were not plainly schizoid but rather of good-natured bearing In families to which the formal pictures of the psychoses of two related members were very similar the author encountered cases referable as regards their symptoms to the manic depressive constellation He finds himself unable to assume a tendency to dementia from an appearance of it in a family for two cases ending in dementia rarely occurred in the same family Cases with a schizophrenic ancestral strain ran on the

average a somewhat milder course and in no instance was it more severe than in those without a schizoid heredity In the face of common contradictory experience the effect of selection has to be considered It was observed that the schizoid patient and the schizophrenic occurred among the children of parents who were not schizoid While the majority of the eccentrics among the relatives of the schizophrenics in Bleuler's series were typically schizoid the frequency of moral defectives was also striking Moreover he found persons in whom the schizoid state was only apparent during a certain period of their life He observed cases which exhibited mild uncharacterized disturbances in involution which left behind them a permanent character change without specific schizoid traits Instances of alternating personality were also present among the relatives An expectation of schizophrenia among the relations of schizophrenics was found to be no higher than 4 5 per cent

Obstetrics and Gynaecology

20 Uterine Haemorrhage

C F FLEMMING (*Journ Amer Med Assoc* September 5th 1931 p 694) records observations upon uterine haemorrhage in pelvic inflammatory disease in a series of 52 patients It had been noted from a recent statistical study that such conditions occurred in 16 per cent of those who had not passed the menopause Though the literature on the subject is meagre the experience of others indicates that such abnormal bleeding occurs in from 35 to 40 per cent of patients suffering from acute or chronic salpingitis From a detailed study of the author's series of 52 cases it was found that they fell into five clinical groups (1) menorrhagia—15 cases of profuse or prolonged periods with a 28-day cycle (2) polymenorrhœa—15 cases of too frequent periods (3) metrorrhagia—12 cases of atypical irregular bleeding (4) 2 cases in which an onset of continuous bleeding coincided with a normal period and (5) a period of bleeding in 8 cases the onset of which occurred between the eighth and eighteenth days of the cycle The main causative conditions concerned in the production of these various types of uterine haemorrhage associated with pelvic inflammatory disease are interference with the normal uterine contractions due to adhesions and malpositions pelvic hyperæmia endometrius disturbances of ovarian function such as deficiency owing to chronic peri-oöphoritis and hyperæmia and to corpus luteum abscess formation The author remarks that it should be borne in mind that the haemorrhage does not necessarily require specific treatment but that it is the complication of the main lesion in the adnexa which needs attention the incidence of endometritis points to the dangers attending injudicious curetting in such patients

21 Induction of Labour by Puncture of the Membranes

G FITZGIBBON (*Journ Obstet and Gynæcol of the Brit Empire* Autumn 1931 p 495) recommends a revival of one of the earliest methods of inducing labour Cephalic presentation having been proved or if necessary secured by version a moderately stiff swivel of a male catheter is guided by one finger in the cervix to a position 'overs the front of the head the membranes are scratched through by sharp movements and a thin trickle of liquor amnii comes away The head is now pushed up intermittently by the use of the finger in the cervix and an external hand so as to allow gushes of fluid to issue After the mobility of the head has become reduced the patient may be allowed to walk about Twelve hours later if labour has not started scopolamine and morphine are given In FitzGibbon's view the amniotic sac plays no part in dilatation of the cervix labour is induced by pressure of the presenting part on the nervous tissues of the parametrium To puncture the membranes high above the head is therefore a less speedy method of induction FitzGibbon does not hesitate to use his procedure in primiparæ among six primiparæ aged from 23 to 28 the average time required for onset of labour was 2½ hours and the average duration of labour 11½ hours For 17 multiparæ the respective average times were considerably greater The usual indications for induction were the prevention of disproportion or of pregnancy beyond term

22 Evolutionary Determination of the Gestation Period

F COLLORIDI (*Arch di Ostet e Ginecol* August 31st 1931 p 1037) has compared the dimensions of the maternal pelvis the weight of the fœtus and the duration of gestation in large groups of labours with average universally enlarged and universally restricted pelves and in groups of cases of moderately overgrown and giant fœtuses respectively In common with Alfieri and Vaccari he finds that in general the pelvic size the fœtal mass and the gestation time are directly proportional These findings are quoted in support of the theory of Schroeder and of Cuzzi which endeavours to explain on Darwinian lines the determination of the gestation period Stocks tending either to premature or to late labour also tend as the ages pass to die out Fœtuses expelled before the average end of gestation—280 days from conception—have easy birth but being relatively feeble are specially liable to succumb to the strain of extrauterine life Those expelled after 280 days although potentially stronger are apt not to survive their labour

23 Acute Hydramnios

PICOT and GELLE (*Bull Soc d'Obst de Gynécol et Paris* October 1931 pp 598 598) describe two cases of acute hydramnios The first patient a 1-para aged 21 suffered during the seventh month from acute abdominal pain and dyspnœa She was found to have a very large uterine swelling œdema of the legs vulva and hypogastrium and albuminuria with a blood pressure of 200 100 mm The membranes were punctured by a fine trocar and 750 c.cm were withdrawn The fœtal heart now became audible and labour commenced six hours later three litres of liquor amnii were collected The fœtus which died half an hour after extraction weighed three kilograms and showed generalized œdema The second patient a 1-para aged 30 had acute pain and great swelling of the uterus at the end of the ninth month œdema albuminuria and hypertension were absent however The pelvis was almost filled by a tumour which was regarded as a fibroma or ovarian cyst At laparotomy 4½ litres of liquor amnii were removed by trocar from the uterus which had undergone almost half a turn of axial rotation It then became possible to excise the pelvic tumour which proved to be a twisted partially necrotic pedunculated subserous fibroma

24 Spinal Anæsthesia in Gynæcology

According to E VOGT (*Zentralbl f Gynäk* October 31st 1931 p 3173) the difficulty which may occur in lumbar puncture in cases of kyphosis and scoliosis is minimized by (1) preliminary x-ray examination (2) the insertion of the needle in a higher situation—between the fourth and third or even the third and second lumbar vertebræ and (3) the use of a special slender needle In cases of advanced œdema of the back firm pressure will cause the swelling to disappear and the puncture is then as a rule exceptionally easy In vaginal operations aiding of the field by relaxation of the sphincter ani may be prevented by a preliminary tamponade of the rectum In the treatment of respiratory impairment intramuscular injections of lobeline and caffeine are valuable the inhalation of carbon dioxide is most effective and a bag under should always be ready at hand Headache which frequently follows spinal anæsthesia in gynæcological cases is exceptional in parturients W MERTENSEK (ibid p 3178) recommends the inhalation of carbon dioxide during spinal anæsthesia because it diminishes the danger of depression of the blood pressure the incidence of vomiting during and after the operation to 4 and 10 per cent respectively and post-operative meteorism He has not found that it prevents the headache which often follows spinal anæsthesia

Pathology

25 Acidity of the Gastric Juice

C BOLTON and G W GOODHART (*Journ Physiol* October 22nd 1931 p 115) have conducted experiments to determine the variations in acidity of the gastric juice as it flows from the whole stomach during a secretory period comparable with what occurs during the digestion of a meal to ascertain whether there are any variations in the acidity of the juice as it flows from the gastric glands to discover the effects of admixture with mucus and to find out the extent to which the unaided stomach is able to reduce the acidity of gastric juice continuously secreted as is the case in the condition of continuous hypersecretion in the human subject Cats were the experimental animals the whole stomach was used in every experiment the pyloric and cardiac orifices being occluded by ligature and a cannula tied in A fresh animal was used for each experiment decerebrated or anaesthetized with ether the results being precisely the same in either case The animals were fed on milk only for a few days and during the last twenty four hours were isolated from sight and smell of food The gastric glands were excited to secretion by pilocarpine or histamine The results were as follows The average acidity of normal gastric juice at the height of secretion is 0 134 *N* (0 49 per cent) and the inorganic chloride 0 07 per cent As the secretion is beginning the average acidity is 0 082 *N* (0 3 per cent) with a corresponding increase in the neutral chloride The low acidity is in some measure due to escape of neutral chloride at the expense of the acid There may be a slight fall in the acidity with again a corresponding increase in the neutral chloride, as the secretion is stopping When the wave of secretion induced by pilocarpine or histamine has ceased a slow after secretion of gastric juice continues for several hours Such small amounts of fluid are always strongly acid The flow of gastric juice does however stop in the strictly normal state of affairs and the mucous membrane becomes alkaline Mucus is secreted in varying amounts during the flow of gastric juice and is most in evidence at the end of the flow it has an alkalinity of about 0 039 *N* (0 14 per cent) and contains 0 28 to 0 36 per cent inorganic chloride The mucus both dilutes and neutralizes the acid of the juice but effects no great reduction in acidity until the flow of juice has actually stopped The unaided stomach has no means of lowering the acidity of the gastric juice secreted into it the gastric secretion continued with undiminished acidity although it was allowed to accumulate in the stomach

26 Hourly Variations in Protein Metabolism

L AMBARD F SCHMID and J STAHL (*Bruxelles Medical* October 18th 1931 p 1476) record the results of certain investigations into the hourly variations of protein metabolism The individuals under observation were kept without food for a period of 24 hours although not starving they were therefore not adding to their nitrogenous stores The first observations made were on the elimination of urea in the urine The usual curve of urea excretion consisted of two parts The first showed a gradual descent until a point was reached where the excretion became constant and the charted line correspondingly horizontal this marking the start of the second part It was observed that the moment of the change from the descending curve to the horizontal line was the time at which the individual *experienced hunger* When hunger was felt from the beginning of the period of observation it was noticed that the chart of the urea excretion was also on a level from the beginning The investigators suggest that hunger may be the means employed by the body to maintain the protein metabolism at an optimum level Since the urea excretion depends on the urea concentration of the blood which remains invariable a direct measurement of the protein metabolism is obtained when the line is horizontal The body tissues are depleted in order to keep the blood urea constant The descending curve of the urea excretion corresponds to the sum of two urea factors (1) the continuing manufacture of urea by the body and (2) the previous accumulation in the tissues By means of calculations the approximate amount of urea manufactured by the body in a given time can be estimated The authors conclude that during the hours when the urea excretion is variable an examination of the urinary urea alone is not a true indication of nitrogenous metabolism

27 The Ultravirus of Tuberculosis

G W SCHMIDT (*Zeit f Hyg u Infektionskrankh* November 1st 1931 p 90) has carried out a painstaking inquiry in an endeavour to confirm the findings of French and Italian workers with regard to the possible existence of a filterable stage in the development of the tubercle bacillus Preliminary experiments demonstrated a number of fallacies inherent in the use of the ordinary earthenware bacterial filters When precautions were taken to avoid these it was still found that isolated organisms in the test cultures of *B prodigiosus* could pass through Chamberland L1 candles Inoculation of guinea pigs with very small doses of virulent tubercle bacilli sometimes resulted in the production of a disease similar to that ascribed to the ultravirus—namely minimal glandular enlargement without any tubercle formation passage experiments from such animals resulted in the production of typical tuberculosis Schmidt's failure to demonstrate the presence of an ultravirus in filtrates leads him to suggest that the lesions ascribed to the ultravirus are in reality due to the presence in filtered cultures and tuberculous products of extremely small numbers of tubercle bacilli he concludes that no satisfactory evidence has yet been brought forward to prove the existence of the ultravirus

28 Vaccination of Cattle with B C G

O BANG I JUNDELL and H MAGNUSSON (*Ann de l Inst Pasteur* October, 1931 p 386) report the results of an investigation carried out to determine the protective value of B C G vaccination against tuberculosis in cattle Calves were used and the vaccinated animals received a single dose of 50 mg of B C G into the subcutaneous tissue of the dewlap These animals together with the unvaccinated controls were infected two to three months later by the intravenous inoculation of 1/100 to 1/50 mg of virulent bovine tubercle bacilli Of the nine control animals four died in five to six weeks of generalized tuberculosis two became ill about 9½ to 11 months after infection and when killed showed advanced lesions three were in good health 9½ to 11 months after infection but when killed they were found to have extensive lesions Of the 13 vaccinated calves six remained free from any tuberculosis as judged by macroscopic examination at necropsy 9½ to 11 months after infection three showed very slight lesions which during life gave rise to no symptoms of disease two when killed 9½ to 11 months after infection had severe lesions, one was killed after 11 months in very poor condition and was found to have very advanced lesions while one animal died of generalized tuberculosis in two months The authors conclude that calves vaccinated subcutaneously with *B C G often* acquire a considerable degree of immunity I JUNDELL and H MAGNUSSON (ibid p 408) record a similar experiment on pigs Eight newborn pigs were given 10 mg of B C G by the mouth on three successive days eight others were vaccinated subcutaneously with a single dose of 10 mg six others served as controls About two months after vaccination the first two groups and the control animals were infected by feeding with a purée of tuberculous tissue from the udder of a cow When killed four to five months later all the animals showed tuberculous lesions of greater or less extent There was no apparent difference in the health of the animals during life or in the severity of the post-mortem lesions between the control and the vaccinated groups The authors conclude that in their experiments there was no evidence of protection attributable to the vaccination

CAESAREAN TWINS

An interesting case has been recently recorded of a mother suffering from extreme pelvic contraction following tuberculous disease of the spine Cæsarean section was performed at the 34th week, and two live children were delivered

The mother was unable to feed the twins and they were brought up on Full Cream Cow & Gate Their progress was uninterrupted, and at the age of 2½ years they each weigh 28 lb

This report is a remarkable testimonial to the value of Cow & Gate, which adequately replaced breast feeding for a mother too delicate to nurse the two children, the twins, moreover, suffered from the disadvantage of prematurity

Reported in the "British Medical Journal" August 1st, 1936

The makers will gladly supply samples for clinical test and any further information required Members of the Medical and Nursing professions are also reminded that the Cow & Gate Laboratories are always at the disposal for experimental work in connection with Milk Foods, and the makers will be delighted to arrange visits to their factories in the West of England at any time.

Guarantee

"We guarantee that all our Surgical Appliances are of the highest quality and workmanship, and undertake to repair or renew, free of charge, any part which may prove defective in material or workmanship within twelve months from date of supply."

Salt and Son Ltd.

One more leaf is turned in the Book of Time, one more year has been lived and is passed, a year during which the House of Salt has knit more closely than ever the bond of good-will and co-operation between themselves and the Medical Profession

We are proud of our standing with all members of the Medical Profession and of the unique reputation of supplying Surgical Appliances of every description which are in keeping with the rapid advances of modern surgery a reputation which we have held since 1793

Another year is now beginning during which we shall endeavour to increase our reputation and to establish more firmly than ever the bond of confidence and good-will that exists between the House of Salt and the Medical Profession

MIST. DAMIANAE CO. (HEWLETT'S).

MIST DAMIANAE CO (Hewlett's) will be found to possess all the properties of Damiana, viz —Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally

In all the various forms of loss of nerve power Mist Damianae Co (Hewlett's) is a powerful remedy relieving the exhaustion and conferring renewed capacity for mental and physical endurance

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required

BRITISH PRODUCTS MADE & SOLD BY A BRITISH COMPANY

A safe and simple antacid which is also a gentle laxative, must necessarily be of great value to the Medical Profession for administration to ladies and children and all who are constitutionally delicate. May we, therefore, venture to remind you of

Extensively prescribed and used by the Medical Profession for a century and still incomparably better and safer than powdered magnesia. Harmless to the most delicate constitution and at all times a mild effective laxative DINNEFORD'S is immensely useful in the nursery too: when mixed with infants food it prevents many of the troubles due to acidity flatulence, etc. As a reliable and safe solution which may be freely used for many ailments we would request your kind consideration of DINNEFORD'S, as occasion offers.

RELIEVES CONSTIPATION

Test Sal Hepatica for yourself and you will agree that it is by far the most satisfactory laxative yet developed There is no pleasanter or more effective way of eliminating from the system harmful toxic amino acids The presence of such evils in the system gives rise to rheumatism, lumbago, neuritis and many other maladies that have their source in auto-intoxication Remember too that Sal Hepatica is essentially non-habit-forming It's daily administration leads to a "time habit" which is invaluable in combating chronic constipation

Sal Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium

the proved, modicinal, **Hepatica**

saline laxative and cholagogue

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Company 12 Cheapside London E C 2

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1 It is made dually fitted to suit the case for young middle aged or old
2 It is simple and true to tone, and leaves the hands free
3 It removes strain thus relieving head noises giving inconspicuous hearing
4 It conveys sound from varying ranges and angles
5 It is entirely different uncopyable and carries a guarantee and service system
6 It is suitable for "hard of hearing" or acutely deaf through various causes
7 It is helpful for conversation, music, talkies wireless home, office, public work and sports
8 A wide range—electrical and non electrical

FREE HOME TESTS
arranged for Doctors and Patients
Medical Prescriptions made up to the minutest detail

"ARDENTE" STETHOSCOPE
Mr P H Dent makes a Stethoscope specially for members of the medical profession suffering from deafness Many are in use and excellent results are reported on the latest as evidenced by the interest shown at the last B M A Meeting

MEDICAL REPORTS
Commended by all leading medical journals—Mr R H Dent will be happy to send full particulars and reprints on request and also arrange demonstrations

IS IT FAIR to your best friend to make him your Executor? The duties are onerous, and usually thankless, the responsibilities are great and the penalties for neglect are severe. Moreover, he may die, and the expense of appointing his successor is considerable. On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee

Ask for the Executor and Trustee booklet at any local branch or call at

WESTMINSTER BANK LIMITED

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent DANIEL F. P. LEAKE, M.A., M.D.

This registered Hospital is situated in 100 acres of park and pasture grounds. Voluntary patients who are suffering from mental disorder, or who wish to prevent recurrence of same, should apply for immediate admission and consult the Superintendent. Patients may be received for temporary residence and examined and advised as to treatment. Careful clinical, bacteriological, and pathological examinations undertaken. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

The Reception House and Hospital grounds, with a private entrance, by which patients can be admitted, is equipped with all the appliances for the most modern treatment of Mental and Nervous Disorders. It contains special departments for electric-light baths, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electric bath, Massage, etc. There is an Operating Theatre and Dental Surgery, an X-ray Room, and Laboratory. Apparatus and a Dark Room for Diathermy and High Frequency treatment. Full occupation for both mental and bodily health is provided for patients.

MOULTON PARK

Two miles from the Main Hospital there are several branch houses, some detached and some in a park and farm of 600 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards. Moulton Park Occupation Farm is a feature of this branch, where patients are given every opportunity for occupying themselves in farming, gardening, and market gardening.

BRYN-Y-NEUADD HALL

The Mansion House of St. Andrew's Hospital, Northampton, and Park of 500 acres, is a Landmark and one of the finest scenery in North Wales. On the North-West coast between Harlech and Portmadoc. Pleasure Parties may visit the branch, a short train journey from Northampton. The Hospital has its own private fishing, boating, and bathing. There is tennis on the Park.

The Hall is the headquarters of the Hospital Farm, which includes arable and pasture grounds. Light manual work (grass and field cultivation) and gentle exercise are provided for patients. Ladies and gentlemen have their own gardens and grounds. Lawn tennis, bathing, boating, and fishing are provided.

Full particulars may be obtained on application to the Medical Superintendent (Telephone No. 80 Northampton) who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is built and fully equipped on ground of an eminence at short distance from Nottingham, and combines a healthful position and comfortable surroundings with every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week have been reduced to from 15 guineas a week

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures the ordinary x ray examinations and electrocardiograph readings, all treatment that may be prescribed such as special diets insulin, artificial sunlight, electrical treatment, baths, massage, nursing medicines or vaccines board and lodging

The only extra charge is that for a complete alimentary x ray examination, or for x ray therapy

Many people who would go abroad for health will not do so this winter All the usual forms of treatment are given at Ruthin Castle The climate is mild The annual rainfall is 30 5 inches, that is less than the average for England There is central heating throughout Should the accommodation in the Castle not prove sufficient comfortable rooms can be obtained near by for those undergoing treatment

Station Eden Park (Southern Railway)

President LORD WAKEFIELD OF HYTHE C B E LL D
Treasurer SIR LIONEL FAUDEL PHILLIPS Bart
Physician Supt J G PORTER PHILLIPS M D F R C P

This Registered Hospital is now situated at Monks Orchard in some 250 acres of park pleasure and farm grounds
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition
With a view to early treatment voluntary or uncertified patients are admitted
Patients who can contribute 3 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit In this Unit is found the X ray and Dental Departments and the Bio Chemical Pathological and Psychological Laboratories
Furthermore provision is made for Electro Therapy and Hydro Therapy to be carried out in all their forms
In addition to the Resident Medical Staff Consultants in special branches of Medicine and Surgery are available whenever required
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms
For forms and further particulars apply to the Physician Superintendent at the Hospital.

Sudan Government

WELLCOME TROPICAL RESEARCH LABORATORIES, KHARTOUM

Applications are invited for the post of BACTERIOLOGIST at an initial rate of pay £E.600 or £E.720 per annum (according to age and qualifications), with five or six biennial increases to £E.1,080, and thence after three years to £E.1,200. These rates of pay as well as the conditions of service are subject to Government rules and regulations from time to time in force. (£E.1 = £1 0s. 6d.)

Applicants must be unmarried and will be expected to take up their duties immediately.

Applications stating age, degrees, experience (with special reference to Pathology), and copies of testimonials should be sent to the Director, Wellcome Tropical Research Laboratories, Khartoum, Sudan.

Further particulars regarding this post may be obtained on application to the Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, London, S.W.1.

The Board of Control (Lunacy and Mental Deficiency)

invite applications for the post of MEDICAL SUPERINTENDENT (male) of RAMPTON STATE INSTITUTION FOR MENTAL DEFECTIVES, near RETFORD, NOTTS. Salary, £1,000, rising by annual increments of £50 to £1,200, together with cost of living bonus which at present is £146 9s. on salary of £1,000. The emolument of a house or rent free is also allowed.

Candidates must be registered Medical Practitioners, must have had experience of the Institutional care and treatment of patients suffering from mental defect or mental disorder, and must conform to the Civil Service nationality rule. Post is pensionable under Civil Service Superannuation Act.

Forms of application with further particulars can be obtained from the Secretary, Board of Control, Caxton House West, Tothill Street, London, S.W.1, and must be completed and returned to him not later than Jan. 30th, 1932.

University of the Witwatersrand, JOHANNESBURG

SENIOR LECTURER IN ANATOMY

Applications are invited for the above post from medically qualified candidates. The teaching embraces Histology in addition to Gross Anatomy.

The salary at present offered is £516 per annum rising by annual increments of approximately £26 to £726 per annum, but these rates may be affected by the financial position of the country, and candidates who have applied will be informed of any reduction which may take place.

Participation in the University Teachers Provident Scheme is compulsory. This scheme provides for a contribution by the members of 6 per cent. of their basic salary (£450—£25—£650), the fund contributing the same amount. A higher commencing rate of salary may be approved in the case of a candidate possessing special qualifications or experience.

An amount of £60 will be allowed for travelling expenses, and half salary paid from the date of embarkation to the date of arrival in *Johannesburg*.

The appointment, which is a full time one, is subject to all the conditions and rules now in force, and duty is to be assumed as soon as possible after appointment, which will be communicated by cable.

Further particulars as to the conditions of service may be obtained from the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, 73 Strand, London, W.C.2, from whom forms stating the particulars required may be obtained.

Applications in duplicate, accompanied by testimonials, should reach the High Commissioner's Office not later than Jan. 15th, 1932.

Surrey County Council

COUNTY SANATORIUM, MILFORD, SURREY (300 Beds)

Applications are invited from qualified and registered Medical Practitioners for the post of THIRD ASSISTANT RESIDENT MEDICAL OFFICER at this Sanatorium.

Candidates should be under 35 years of age and have held resident hospital appointments. Sanatorium experience is not essential.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act 1922, and the successful candidate will be required to pass a medical examination. Termination of engagement will be at one month's notice on either side.

The salary is £350 per annum, together with board, lodging, and laundry. These emoluments are valued at £100 per annum for purposes of Superannuation.

This salary will be subjected to an emergency abatement of £15 per annum.

The appointment will be made in the first instance for a period of six months, renewable at the end of that period for a further six months.

The successful candidate will be required to devote his whole time to the services of the County Council.

Forms of application may be obtained from the County Medical Officer of Health, County Hall, Kingston-upon-Thames, to whom completed application forms must be returned, together with copies of three recent testimonials, not later than Saturday, January 9th, 1932.

DUDLEY AUKLAND,

DURING PREGNANCY

IN the preparation for motherhood  be the patient a young primigravida  or an experienced multigravida  slim and delicate  or generously built  besides the routine tests  among your urgent instructions  will be

"Regular bowel movements daily" That will prevent many a headache, feeling of lassitude, and perhaps hæmorrhoids in the later months You can prescribe AGAROL safely, because it exerts no effect upon the uterus nor does it interfere with lactation Besides it is easily taken because it is palatable without artificial flavouring

A supply gladly sent for trial

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein It softens the intestinal contents and gently stimulates peristalsis

AGAROL BRAND COMPOUND *for Constipation*

This offer is only available to doctors in Great Britain

YOU can give a word of caution with advantage when you are prescribing China tea.

Patients do not as a rule distinguish between *pure* China tea and mixtures of ordinary teas with China tea

Only *pure* China tea has the medicinal properties that make it of value in the treatment of digestive disturbances

The words pure China on a packet ensure this

Brooke Bond *pure* China Tea 3/- lb

Any grocer can easily get it

THE IDEAL SEDATIVE

ÉLIXIR BROMO-VALERIANATE GABAIL

Progress . . .

A 1932 announcement

IN a period of economic stress everyone must choose between a bold progressive policy or retrogression There is no standing still

This Company has always pursued a progressive and constructive policy We have always been pioneers

This year we are making early announcement of several fresh radical important developments in equipment for Actinotherapy These have significance for every practitioner keen to keep abreast of modern work

Several new Hanovia Lamps will shortly be available to the medical profession They will conform in every detail to our standard policy of all-British manufacture In each instance the new models will embody modern design, improved finish better service and greater value for the prospective user

To secure advance information please use the coupon below

"EATAN"

AMINO BEEF BEVERAGE

(Eaton Amino-emulsified-extract)

Entirely supersedes Pancreatised and Peptonized Foods.

May be taken in water milk, soups and beverages generally.

Sample to Medical Men on request

Eatan is a concentrated extract prepared by the ultimate hydrolysis of ox proteins and organs to the amino-acid stage, presenting nutritive, constructive, and stimulative factors in their simplest and most easily assimilable forms.

Also contains the allied Hormone constituents of the principal glands.

The administration of Eatan is specially indicated in debility associated with Malnutrition, Anæmia, Febrile conditions, Marasmus, Chronic Gastritis, Osteomyelitis.

Its administration may be continued over long periods without complications or the slightest irritation of the digestive tract.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease through eliminating deleterious nitrogenous products and favourably influencing circulation glandular secretions peristalsis and metabolism

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal

How Gibbs Educational Service promotes the Interests of the Doctor

New Light upon an Old Subject

Most recent among the activities of D & W Gibbs Ltd is the publication of a Teachers' and Parents' text book of unusual interest In 'Your Teeth' the subject of the human teeth is reviewed from prehistoric days down to the present, and there are informative notes on the correct use of the tooth-brush, prevention and treatment of dental caries, pyorrhœa, systemic poisoning from teeth, facial appearance, etc

Approved by the Institute of Hygiene and by an eminent Dental Surgeon, this Book is unexpectedly popular Supplies are at your disposal for issue as you may see fit, with samples of Gibbs Dentifrice

Full particulars of Gibbs Educational Service (literature, propaganda material, cinema films, lecture charts and other school-room aids), as well as clinical samples for tests, are gladly sent free upon request to any member of the Medical or Dental Profession on receipt of professional card

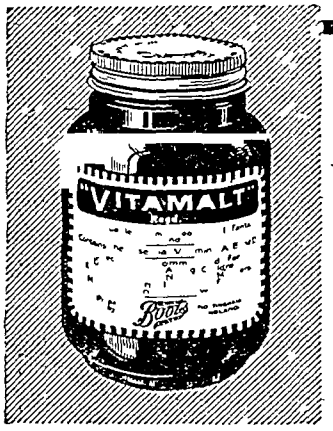
SONERYL

TRADE MARK



Powerful Hypnotic and Analgesic

An agent which has the double advantage of relieving pain and inducing sleep is invaluable in everyday practice

'Soneryl' adequately meets this need and is widely employed for insomnia whether arising from painful affections or febrile or nervous states

"Soneryl" produces no after-effects nor does it lead to habit formation

Prepared in the Laboratories of
MAY & BAKER LTD.
BATTERSEA LONDON S.W.11

VITAMALT

Containing Vitamins A, B and D

A well-balanced food which ensures an adequate supply of these essential vitamins and which corrects disorders arising from deficiency of these important bodies

Vitamalt has been skilfully blended to make a preparation which is easily assimilated and provides an acceptable form of vitamin medication

During expectant and nursing motherhood Vitamalt provides a plentiful supply of vitamins and is a valuable aid to nutrition during this important period

. . gratifying results in the treatment of

LEUCORRHOEA *(incipient and chronic)*

Physicians are invited to apply for full particulars and clinical sample to the manufacturers

Very gratifying results have attended the use of Monsol Pessaries in the treatment of both incipient and chronic leucorrhoea, and in kindred catarrhal conditions

Prepared on a glyco-gelatine base containing the equivalent of 2½% Monsol in a colloidal form, Monsol Pessaries are actively germicidal in the presence of organic matter, absolutely NON-CAUSTIC to the delicate tissues, and deeply penetrating These properties are doubtless the explanation of their success in combating these conditions

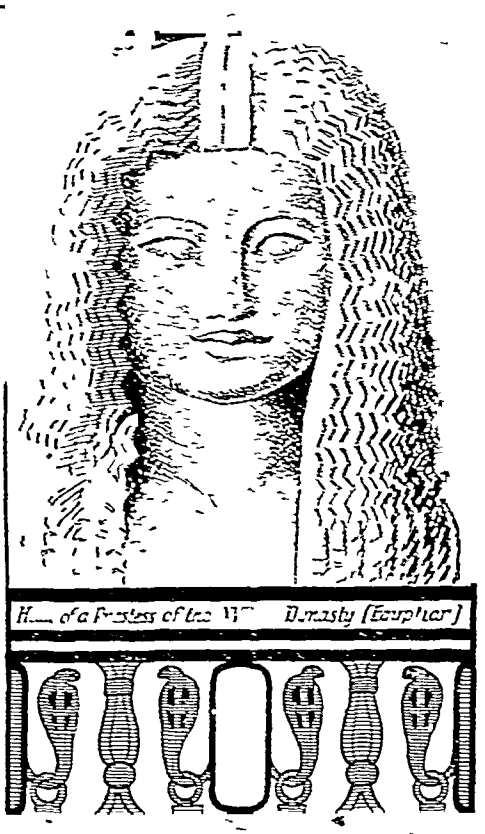
OVALTINE

FOR THE AGED

Ovaltine is delicious sustenance for old people. It sustains life ideally by giving tone to the tissues and promoting the healthy activity of the bodily functions

Ovaltine provides complete nourishment in easily assimilable form Its use greatly increases the nourishing value of other foods The digestibility of milk, for instance, so largely used in old age, is increased two-fold by adding Ovaltine to it, while the starch in the cereals is converted into easily assimilated malt sugar by the enzyme diastase which Ovaltine contains in abundance.



Ovaltine is purin-free. Its use therefore, neither aggravates nor favours the accumulation of uric acid in the system nor leads to kidney disorder or gout. The tendency to constipation so common in old age, is avoided by the use of Ovaltine

Ovaltine" replaces to great advantage the usual meal-time beverages tea and coffee, which are valueless as sources of nourishment and often contraindicated in senility

Reaching Laryngeal and Bronchial Inflammations

MANY laryngologists are advising the treatment of laryngeal, tracheal and bronchial inflammations by the direct route, nebulised spray solutions—in addition to the use of oral medication.

[illegible] results are due to three forms of administration. When [illegible] nebuliser forms an expanding fine cloud, invisible to the eye. This cloud is drawn [illegible] to the upper respiratory passages and is drawn into the larynx and trachea with each inspiration. In this way it reaches and exerts its therapeutic action on all the upper respiratory tract.

The nebuliser of Mistol—menthol camphor eucalyptol and cetrimide in base of liquid paraffin—is employed by all leading laryngologists.

They relieve congestion and hyperæmia of inflamed mucous membranes, diminish abnormal secretion, and assist the return to normal conditions.

Where more physiological findings in Mistol commend [illegible] by means of a nebuliser a valuable ally to oral medicaments in laryngeal, tracheal and bronchial inflammations.

Local Anæsthesia in Surgical Practice

RUPTURED KIDNEY WITH INFECTED HAEMATOMA

Typical Case

Operation Incision, drainage and suture of the Kidney

M. H. D., aged 21 years

Anaesthesia Local infiltration block

History The patient had been injured in a motor cycle accident. He was extremely tender in the region of the left kidney, and his urine showed a large amount of blood.

Technique of Anaesthesia A classical infiltration was made, using 150 c.c. of a 0.7 of 1 per cent. Novocain Adrenaline solution. A transverse incision was made and a retroperitoneal haematoma opened and drained. One litre of dark clotted blood and urine was evacuated. The kidney presented at the base of the cavity and showed a transverse rupture about the midline. By means of perfect retraction, a good light and a long needle holder, the two halves of the kidney were sutured together with chromicized gut without disturbing the organ. Drainage tubes were introduced and the wound closed. The boy made an uneventful recovery and presented a normal urine within two weeks after the operation.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr)

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work published by Henry Kimpton 263 High Holborn London W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation

Does not contain Cocaine, and does not come under the Dangerous Drugs Act

And all the leading Surgical Equipment Houses

treated scientifically rather than empirically If we look closely into this development we recognize at once that it has been largely due to the realization that the genital organs and functions are not limited to the pelvis, but are in fact in intimate correlation with all the regulators of metabolism, as Noel Paton has called the ductless glands, and with their influences It was to this fascinating question that I was first attracted over twenty years ago From it such important matters as the final differentiation of sex, the mechanism of menstruation the physiology of conception and the phenomena of the menopause have passed into everyday knowledge and teaching This widening of our sphere has brought us into the closest touch with general medicine and surgery

Many interesting examples of advances along these lines of investigation might be quoted For instance the gynaecologist is sometimes the first to diagnose pituitary dysfunction as the result of his investigation of a case of amenorrhoea whereas, when many of us were students such patients received myrrh, aloes, and iron! Again Aschheim and Zondek have fruitfully exploited our knowledge of the correlations between the pituitary ovary, and placenta, and have shown that in the urine of pregnant women a biochemical substance which can be identified by simple biological tests is excreted This culmination of scientific endeavour has given to the world one of the most beautiful diagnostic reactions ever placed in the hands of the profession I believe too that it will be the precursor of many tests based on metabolic interactions both in normal and abnormal states It is in fact not a late comer but a forerunner Yet even this discovery has left unsettled various problems in connexion with it The most important of these is the question Why cannot prolan B be identified in the urine of pregnant lower animals? Here is what appears to be a not very difficult investigation and one that might lead to interesting developments * Furthermore of the general metabolic studies of ourselves and others we have not been slow to take advantage The importance of the calcium metabolism in respect of the genital functions in normal and in abnormal states is now universally recognized So too knowledge of the influences of the vitamins due chiefly to the researches of the biochemist Gowland Hopkins has led to a great improvement in the management of pregnant women Indeed it appears likely that if obstetricians of the rising generation will seize the chances awaiting them along these lines their efforts may lead to the disappearance of all the grosser malformations of the pelvis and of certain metabolic disturbances with which we are confronted to day But above all it seems to me that the tremendously successful outcome of long trials of scientific endeavour with their dramatic and immediate clinical applications must fire the imagination and ambition to excel in many of our younger colleagues This it is true is a preventive era but prevention necessitates action as well as masterly inactive measures We cannot make the sun shine but we can remove obstructions to its rays and even utilize artificial sunlight Here we have an illustration of the beautiful simplifications that follow in the wake of abstruse science so well exemplified in the recognition of the fact that the essential vitamins are constituents of our common food stuffs A great enlightenment this for it confirms our belief in Nature and in the naturalness of the phenomena of life growth and health with which our science is connected in a most intimate way

I have just tried to indicate in the manner of my telling that the clinical application of discoveries —shall I call them?—often takes a very simple form for we find that many errors of metabolism can be avoided or rectified by the use of natural materials and processes We can prevent and treat rickets for instance, by ensuring that the individual leads a sunlit lactivorous, vitaminous life So much, then, for our present kind of knowledge I have made no attempt to do more than illustrate the way in which it has been acquired and should be utilized, and to indicate how the vast amount of scientific work done of recent years is bringing our knowledge, obtained in different fields of inquiry along convergent lines to clinical foci This means that he whose mental accommodation is swift and sure will so align the rays of light that they fall upon and illumine what was hitherto obscure But for this careful preparation is necessary It is essential that we organize our methods and our means both individual and environmental So called 'genius' as is well known lies not so much in great natural aptitude as in the capacity for taking infinite pains to ensure that good results shall follow the operations of the mind The vision to foresee the equipment and facilities required, and the knowledge of how best to order our own thoughts and the thoughts of those who follow after us, constitute the fundamental attributes behind human endeavour and progress

* In this connexion reference may be made to the statements contained in a letter published since this lecture was set up in type Laquer L *British Medical Journal* 1331 ii 1165

TEACHING AND LEARNING

Principles of Teaching

As we look around the country we notice that medical teaching schools attached to universities have come into being in every large city This means that everywhere teachers have appeared whose guidance is sought by many students who in older times would never have taken up the most difficult, and owing to the variable factors concerned the most intimate and personal of all sciences The whole gamut of human attributes is drawn upon for the perfection of the medical scientist and every practitioner is or should be a medical scientist whether he appreciates his position or not His sensibilities his memory, and his higher faculties of analysis and judgement imagination and creation are constantly called into action This is *recognized* by all teachers who take the trouble to study their responsibilities not but that in the days long past the great teachers who were then so few in number must by some intuitive method have taught as though they had given much thought to the manner of so doing We are, however, very reticent about these matters we feel when we discuss if ever we do abstractions of this kind that we are treading on holy ground, and that the subject is one for personal contemplation rather than for public consideration Yet I am convinced from what I have seen that the teaching of obstetrics and gynaecology in these islands is generally speaking more idealistically (in the philosophical sense) practised than is that of the kindred subjects of medicine and surgery The reason for this lies undoubtedly in that happy blending of science practice and service to the frailties of womanhood which forms the environment in which we obstetricians and gynaecologists have our being By these perhaps crudely expressed thoughts I want to convey the view that in teaching our students and nurses —our colleagues to be—we should strive to make them thought conscious rather than self-conscious and self sufficient With the vast growth in our knowledge of the scientific aspects of our branch of medicine with the different nature of primary and secondary teaching as contrasted with the classical and philosophical education to which practically all of us were apprenticed in the nineteenth century and with the somewhat different material psychologically considered that is committed to our charge we must all the more inculcate the necessity for right ways of thinking and for discipline of the mind

I have recently discussed brains [1] their constitution and education Though I must not here delve into psychological problems I may perhaps insist that a

treated scientifically rather than empirically If we look closely into this development we recognize at once that it has been largely due to the realization that the genital organs and functions are not limited to the pelvis but are in fact in intimate correlation with all the regulators of metabolism as Noel Paton has called the ductless glands, and with their influences It was to this fascinating question that I was first attracted over twenty years ago From it such important matters as the final differentiation of sex the mechanism of menstruation the physiology of conception and the phenomena of the menopause have passed into everyday knowledge and teaching This widening of our sphere has brought us into the closest touch with general medicine and surgery

TEACHING AND LEARNING

Principles of Teaching

As we look around the country we notice that medical teaching schools attached to universities have come into being in every large city This means that everywhere teachers have appeared whose guidance is sought by many students who in older times would never have taken up the most difficult and owing to the variable factors concerned the most intimate and personal of all sciences The whole gamut of human attributes is drawn upon for the perfection of the medical scientist and every practitioner is or should be a medical scientist whether he appreciates his position or not His sensibilities his memory and his higher faculties of analysis and judgement imagination and creation are constantly called into action This is recognized by all teachers who take the trouble to study their responsibilities not but that in the days long past the great teachers who were then so few in number, must by some intuitive method have taught as though they had given much thought to the manner of so doing We are however very reticent about these matters we feel when we discuss if ever we do abstractions of this kind that we are treading on holy ground and that the subject is one for personal contemplation rather than for public consideration Yet I am convinced from what I have seen that the teaching of obstetrics and gynaecology in these islands is generally speaking more idealistically (in the philosophical sense) practised than is that of the kindred subjects of medicine and surgery The reason for this lies undoubtedly in that happy blending of science practice and service to the frailties of womanhood which forms the environment in which we obstetricians and gynaecologists have our being By these perhaps crudely expressed thoughts I want to convey the view that in teaching our students and nurses —our colleagues to be—we should strive to make them thought conscious rather than self conscious and self sufficient With the vast growth in our knowledge of the scientific aspects of our branch of medicine with the different nature of primary and secondary teaching as contrasted with the classical and philosophical education to which practically all of us were apprenticed in the nineteenth century and with the somewhat different material psychologically considered that is committed to our charge we must all the more inculcate the necessity for right ways of thinking and for discipline of the mind

I have recently discussed brains [1] their constitution and education Though I must not here delve into psychological problems I may perhaps insist that a

retentive memory is not all that is required in a student even though it enables him to shine in examinations. More and more from our teaching experiences we recognize that if we can fix the attention and interests of our pupils and demonstrate to them that *learning is understanding* not only will they not forget—and we have all noticed that students never forget the unusual and curious—but also by proper appreciation of principles lucidly explained they will acquire the habit of thinking and finding out for themselves. Yet among the army of teachers even teachers of obstetrics and gynaecology there cannot but be some who confine themselves to the teaching of facts alone and so produce an index type of mind. They evoke no gleam of mental satisfaction in the backward such as comes to those on whom the truth of some hitherto difficult problem has dawned. Some understanding of modern psychology is of the greatest value to every teacher as it is to every practitioner.

Preliminary Scientific Training

At this point perhaps a few words may be said about the teaching of the preliminary sciences in relation to medicine. This has been ably discussed in recent years by Professor J. A. Milroy (1929),[6] Professor R. J. S. McDowall (1931),[7] and others. It is a difficult subject first because the time factor in the medical curriculum has to be considered secondly because there is the question of how and how much of the fundamental sciences should be taught. In regard to the first difficulty what may be called essential knowledge has increased with great speed not only in the fundamental sciences but also in their application to clinical practice. Further purely clinical and pathological knowledge has progressed so far in every direction that the lengthening of the time of the medical curriculum alone has been unable to meet the situation. How then can the ordinary student be expected even step by step throughout his course to become really proficient in all? He cannot possibly be expected to do so. What is the alternative for it is generally admitted that a useful knowledge both of the preliminary sciences and also of medicine is necessary. At the same time it must not be forgotten that we are obliged to cater for students of average ability and not for the few brilliant men.

It does not seem to help us much to dwell on the growing independence of the sciences in relation to what McDowall terms "vocational sciences"—in our case medicine—unless our object be to show that this is at the root of the trouble that has arisen. It is of more importance for us to find a way out of our difficulties and it would seem that this can only be by way of simplification. So it is borne in upon us that from the practical as well as *from* the psychological standpoint the teaching of detail should be curtailed as far as possible and the teaching of principles expanded. Too detailed knowledge is positively harmful to those with retentive memories for such students become walking indices relying on the efforts of other brains instead of using their own. It is far better to teach students the underlying principles and to show the relation of these to the more important details in order that they may fill in the rest for themselves. For this reason all the preliminary sciences—and I differ from those who would exclude botany—should be taught in such a way that the application of them to principles of medicine would be made so clear and interesting that they could not fail to become fixed in the student's mind. If I may be permitted to touch on my own experience I may say that I have found my own interest in human and comparative morphology physiology and pathology of much assistance in teaching students for they are always greatly interested in the relationship between evolutionary and other biological principles and their human studies and that is why in my *Principles of Gynaecology* comparative anatomy and physiology receive consideration. If the teaching of the preliminary sciences were concentrated in this way and unnecessary detail avoided our students would come to their final studies knowing how to think understand and apply and we should not have our curriculum overcrowded by the unending enumeration of facts that must be memorized. Naturally if most anatomists and physiologists regard their subjects as the most important they aim at making all students acquire a comprehensive and much too detailed knowledge of them. As a result in some medical schools physicians and surgeons have been appointed to teach applied physiology and anatomy in order to alleviate the mental indigestion caused. This attempt at correlation can hardly be considered a satisfactory solution. We obstetricians and gynaecologists however since we have been compelled ourselves to work at the preliminary sciences which have a bearing on our vocational science have been better fitted than our colleagues in other branches of medicine to teach our students the essential principles of morphology and physiology in relation to our subject indeed had we not been they would never have learned them elsewhere. This is one of the chief reasons why we should continue to do scientific work in connexion with obstetrics and gynaecology.

Arrangements for Teaching Obstetrics and Gynaecology

The application of the methods of teaching to which attention has been called should receive serious consideration. Yet it is important that the main features should not be obscured by disputations concerning local arrangements which after all are chiefly related to individual preferences to different estimates of the aptitude of students generally and to the facilities obtaining in various university centres. Every teacher for example should be allowed to teach his students by the methods from which he obtains the best results. Some men can create interest by lecturing others by class instruction and so on. Consequently it should be ordained in the future that a university syllabus shows only the times allotted to theoretical and practical teaching and not to the methods. To make a poor lecturer lecture is to invite imperfect and ineffectual teaching. This seems common sense just as does the fact that if there are only 200 maternity cases available for each rota of twenty students only ten cases can be personally delivered by each but it can also be insisted that each student shall be present at and closely observe fifty deliveries. In other words while adhering to a general desideratum we should allow of elasticity in the manner by which it is reached. It is nevertheless wonderful how much uniformity does exist at the present time when we remember that it is not many years—not more than about ten—since the teaching requirements in obstetrics and gynaecology were ridiculously inadequate and were even then evaluated by non-fulfilment without compensation for example compliance with the regulation that each student should personally deliver twenty maternity cases was in many places impossible. At last a movement is in progress to secure that the *time* of the student allotted to obstetrics and gynaecology shall be at least as long as is possible under the present period of medical study. It will be our duty to see not only that this is well applied but also that we have the proper facilities for the purpose. Until there is uniformity in the facilities in each teaching centre in proportion to the average number of students it will be very hard to obtain standardization in regard to the manner in which the general requirements are carried out. At the same time we cannot forget that it is the duty of every teaching school to turn out highly efficient practitioners whatever may be the ultimate conditions of practice.

Material Facilities—There is little doubt that both for our own efficiency in regard to scientific and clinical work and for educating the student a suitable environment, with all the necessary facilities is most desirable In this country we have never in a general way organized our teaching school and research arrangements in the thorough manner some of our European and American colleagues have done I know of only two university departments worthy of the name in Great Britain and one of them is in this city These go far beyond anything that has been attempted by the physicians and surgeons There are I am glad to say one or two more in embryo the growth of which we shall all watch with interest On the other hand so far as arrangements and facilities for purely clinical teaching are concerned most of us by personal endeavour have secured satisfactory clinical departments and operating theatres This has not always been easy when the improvements necessary have been advocated in general hospitals under the often jealous eyes of our surgical colleagues for we have not yet completely established to their satisfaction our right to be regarded as their equals

The recognition of the advantages which have been set out elsewhere - of having large obstetrical and gynaecological departments in general hospitals need not be reiterated here but apart from the wider outlook and the increased facilities for teaching thereby afforded, this arrangement tends more than anything else to place gynaecology and obstetrics on the same footing as that of medicine and surgery for it brings the gynaecologist and obstetrician away from his isolated position in a special hospital to close work and co operation with his other colleagues It is to be hoped therefore that the future will see the gradual disappearance of special hospitals

There are one or two aspects of clinical teaching to which some reference is necessary It has rightly been held that whereas the general practitioner is not expected to perform the major operations of general surgery (although he often does so) he may be called upon to deal with a major complication of labour This is the present state of affairs but is it one of which we really approve? Is it not rather one which we condone? Does the training advocated now by the most importunate of us—that is four months of clinical obstetrics (two of which shall be spent in residence) and two months of clinical gynaecology—does this make every student fit to conduct a major obstetrical operation? Few of us would agree that it does so although it may be enough for the occasional brilliant student It could on the other hand well be argued that it gave a confidence which might lead to dire results The inwardness of my remarks will be clear to all teachers who know how little operative work such students can obtain under present conditions It can be estimated then that while the teaching arrangements soon to come into force almost everywhere in this country will give students as good a training as they obtain in medicine and surgery it certainly will not fit them to become either obstetrical specialists—which is what the public seems to demand—and still less gynaecological experts It is said that obstetrical complications are emergencies They used to be but with proper ante natal care this is only occasionally the case to day So without going into particulars it may be stated that in the immediate future we must establish an adequate maternity service staffed by properly trained men and if the organization is to be efficient it must be allied to and dependent on the teaching units It must not be a national service within the public health service - The time may come when all practitioners undertaking maternity work in such a service will be required to possess a diploma or a higher qualification in obstetrics and gynaecology after an adequate period of post graduate study This should be one of our immediate aims

Post graduate facilities are rare and hard to secure in this country though in Manchester as we know there is an excellent scheme for post graduate obstetrical work Such courses should be more general, more continuous more in demand, and the practical work conducted by the post-graduate student himself should be more extensive and varied The development of post graduate teaching and the facilities for practical experience under university control is an urgent problem to day and it is being seriously undertaken in a few centres only Yet we can not expect a very great demand for post graduate courses in the present circumstances of practice in this country The heavy financial burden thrown on the practitioner by absence from his practice while undertaking post graduate study, and the exacting nature of this course in obstetrics will require careful consideration The possibility of some form of compensation such as a diploma is the least that should be offered

EXAMINATIONS

The whole system of examining—the system of mental tests—that we apply to our students is causing anxious thought to many Just as our methods of teaching—established long ago by and for the few who were educated in a more formal and classical age—are not always congenial to the modern teacher so it is that our methods of examination which have endured for a century may not be altogether suitable to modern requirements It is true that all scientific men must have a theoretical as well as a practical training This was recognized by the Brahmins several centuries B C

> He who is trained only in theory and is not experienced in practice knows not what he should do when actually dealing with a patient on the other hand a surgeon who is educated in practice alone and knows nothing of science will not earn the respect of better men

It is desirable that all doctors should show that they have had a good general education Facility of expression is an important indication of brains ' So we test the theoretical knowledge and the powers of analysis and expression in good English by means of papers This is a right method and should be retained The results, however are often lamentable in regard to arrangement grammar, punctuation methods of expression and legibility of handwriting putting aside the question of knowledge displayed I fear that we are all too lenient in regard to this part of the examination and perhaps do not realize all we should look for in such a mental test If the assessment were rigid I imagine that only about 10 per cent of candidates at the very most would be found to write papers that could be regarded as satisfactory But in some measure this is our own fault How many students in the whole of their medical careers receive instruction in the proper methods of demonstrating their knowledge on paper and at viva voce examinations? Recognizing this for a number of years I have given to my students one or more lectures on how to learn and how to utilize knowledge and I have constantly discussed these matters during class instruction I hope the future will see a development along these lines and that students will be taught this important aspect of learning early in the curriculum

The clinical examination if properly conducted is most valuable but it would probably be better if more time were spent on it The difficulty lies in the short duration of the whole examination Any large number of students can of course be engaged at one and the same time in writing answers to the questions set in the papers but if two or three hours were to be devoted to the

clinical examination of each student in the two or three days allotted to the whole examination an army of examiners would be required. The same applies to the viva voce examination in pathology which should be concerned only with the relation of pathological appearances and lesions to the signs, symptoms, and progress of disease. In Sweden there is no formal final examination at the end of the seven or eight years medical course. The student is taken by the professor for a couple of hours or possibly for one-half of a day and is questioned orally only. He is called upon to examine and to discuss the diagnosis and treatment of cases, the pathological findings and so on. If the professor, who already knows his man, is satisfied, the candidate is passed in that subject. In most university centres in Sweden, with its small total population of about 6,000,000 persons, the number of students is not very large and with no definite time or date for the examination of each student, it is not difficult for the professor who has no external examiner to consider to manage matters satisfactorily. It has been suggested in this country that in addition to the ordinary examinations the record of each student in regard to his clinical work in the wards should be fully described by his teacher and submitted to the examiners at the final examination in evidence of the candidate's practical capacity and fitness or the reverse. I believe that this arrangement has been adopted in some places. Most teachers and examiners would welcome an extension of the practice if it properly controlled, accepting such evidence in the place of the less complete method of clinical examination now employed.

It appears then that the student should receive definite instruction early in his career as to how to use his hands and to express himself. This would enhance the value of the teaching he subsequently received. It would enable him to do his examinations better and to become a more efficient practitioner. The examination should consist first of a clinical test conducted by two of his teachers between the completion of the candidate's clinical course and the examination proper. If the student fail in this clinical part he should be relieved from competing the examination, for it is a sad waste of time in most universities that a student sadly pass the clinical examination regardless of his paper. This would save the examiners time and they could devote more to the examination of the candidates whose clinical work had been satisfactory. The second part of the examination for these would comprise written answers to the papers and a viva voce test in pathology.

With regard to the examination of post-graduates for the higher degrees and certificates the case is somewhat different. At most universities and colleges in this country conduct these examinations on exactly the same lines as those for students wishing to qualify. This does not seem to be right. If a man enters for the final Fellowship examination in surgery at any Royal College of Surgeons he is desirous of obtaining one of the highest surgical certificates and in many cases intends to follow a surgical career. There should be much more demand therefore for his personal surgical record not only in respect of the resident and other posts he may have had but also of the actual surgical work he has done. For this provision is made in the regulations governing the membership of the British College of Obstetricians and Gynaecologists. Before a candidate can enter for the first examination which consists only of a three hours examination of one hour's duration on any aspect of obstetrics and gynaecology he must submit a record of the posts he has held—a certain minimum being required—together with a record of a certain number of obstetrical cases and gynaecological operations conducted by himself. Moreover an obstetrical and also a gynaecological thesis on some of the cases must be submitted. It is only when these records are accepted that the candidate is examined in the way described.

Clinical Practice

In this sphere we have already attained a very high level of accomplishment. It is not so very long since gynaecologists were regarded as accoucheurs trying to do surgery and obstetricians as midwives. Everyone knows that in certain London hospitals there were until the present generation forbidden to attempt major surgery. We also know how the stunting blight has long remained and indeed has not yet been entirely removed from the gynaecological practice that was so unfairly afflicted. Lawson Tait with his courage and dominance, Alexander with his regard for physiological principles and Donald with his tact, technical skill and wider acceptance and application of scientific advances took prominent parts in the emancipation of gynaecological surgery as we know it to-day and played a part in a critical era of technical perfection. The present generation of gynaecologists old and young has completed the triumph. Among them are men known the world over as craftsmen in surgery no less competent than the most expert general surgeons of the time. Yet we must beware lest we become self-satisfied for there is still too wide a gap between the best and the worst. There is also ample room for improvement among the most proficient and this is related chiefly to perfection of technique and the application of correct procedure all of which require thought and then further thinking.

The greatest advances in gynaecological surgery have been not so much in the technical improvement of radical operations which unhappily are still sometimes necessary as in the development of conservative and reparative procedures. With the latter I have recently dealt and to them I need not again refer but I should be failing in my duty were I not to mention the progress that has been made in the treatment of obstetrical injuries which so often lead to prolapse later. In this campaign Manchester has led the way. It is not for me to say how much credit is due to Doyle, how much to Fothergill or to others but for the Manchester school has spoken with one voice and the rest of the gynaecological world has responded. That obstetrical technique and the prevention and alleviation of therapeutic measures of the disorders associated with childbirth have not advanced at the same rate is to some extent intangible for gynaecological surgery has simply followed the trend of all surgical procedures while obstetrical practice has not had similar opportunities. So it is that many have tried quite wrongly to separate the two parts of our subject, instead of bringing their mental and manual efficiency to the standard required of the Complete Gynaecologist—the man competent to deal with all aspects of the science and art of our comprehensive subject.

Spirit of Obstetrics and Gynaecology

Most of us recognize that what we as a country have done, and so may be during the last half-century that we have not had another time for opportunity only to consolidate our present position and as we have seen there has been a danger of our losing part of our territory. Those who have real interests must press them to their uttermost possibilities that we take ourselves and our subjects seriously and that we are pressing for more than is our just portion. As we have stated gynaecology and obstetrics represents in a way which no other branch of medicine can do the practical side of biology so far as the human subject is concerned. Scientific speaking medicine, surgery and the specialties both in their preventive and curative aspects are extensions of that

branch of gynaecology and obstetrics which concerns child welfare It should not be necessary therefore to establish our own status for we freely grant the acquired status of the daughter branches of our subject, but it seems that it is necessary for in the future we must have our house in order our privileges recognized and our facilities for progress ample and secure There now exists a British College of Obstetricians and Gynaecologists In this institution lies I believe the future of British gynaecology and obstetrics The rapid progress of our College in two years towards the fullest recognition and usefulness may be traced to the fact that all the details of its formation projects and possibilities and the means and performances necessary to bring these to fruition, were fully realized in advance The College has progressed according to plan and not to chance

The younger men who will take the places of those of us who have been concerned in the formation and policy of the College and in establishing its traditions and ceremonies should fit themselves for the task that awaits them Each should accustom himself to envisage not *only his own or immediate local development* but the development of gynaecology and obstetrics generally It should become the firm resolve of all to make our College the guardian in this country of our branch of medicine It should constitute our central organization, both for teaching and applying mental tests to individuals and for assisting and encouraging research, remedying social anomalies within our province, and improving the practice of our art The declaration which all members of the College are required to sign well expresses this ideal

It is always easier to speak of the future which is on the lap of the gods, than to analyse the present, which is before everyone as an actual experience Nevertheless, provided we are capable of framing sound judgements from our experiences and have enough imagination and constructive ability, we should be able to plan to model and to build an edifice, imposing useful, and capable of expansion in the future

That for which we are striving—the recognition of all we are and mean in the advance of medical science—will be consummated if we continue to follow our ideals

[Professor Blair Bell's lecture concluded with a section entitled 'Conditions of practice in the future']

THE ACCIDENTS OF THE MALE CLIMACTERIC

BY

KENNETH WALKER M B F R C S

SURGEON IN CHARGE OF THE GENITO URINARY DEPARTMENT ROYAL NORTHERN HOSPITAL SURGEON ST PAUL'S HOSPITAL

The title of my paper requires some explanation No such condition as a male climacteric is recognized by orthodox medicine In man as opposed to woman there is no well-defined termination to the reproductive function and examples could be given of men who have retained their capacity to procreate in advanced old age Recently I appeared as an expert witness in the law courts in a suit which turned on whether a man of 83 could be the father of a child We won our case not only because the collateral evidence was strong but because I could quote many instances of spermatogenesis in the testes of men of 80 and even of 90 Metchnikoff actually cites the case of a man of 103 in whose testes spermatozoa were found And if examples are required of the retention of sexual passion we have only to think of Goethe who at the age of 74 fell so desperately in love with a girl of 17 that when his suit went badly he was prostrated with grief and no longer desired to live Indeed it was this episode in his life and a previous one in which he had been more successful that suggested to him the theme of *Faust*

But despite these examples of individual men who have retained their sexual capacity in old age I still think that it is possible to talk of the male climacteric The idea is not a new one for long ago Arab and Greek mystics wrote of the grand climacteric which they placed at the age of 63 In medical literature the notion of a critical age for man has also found a place although such eminent authorities as Kraft Ebbing and Vinay have denied that there is any psychological evidence to support it But it was to the term male menopause that Kraft Ebbing was chiefly opposed and as Gregorio Maranon says in his excellent work on the climacteric such an expression as menopause implies an initial error By the word menopause is meant a cessation of the menstrual flow and to use it in reference to the male is manifestly wrong The term climacteric is less linked with the idea of menses and therefore greatly to be preferred but in order to avoid any possible confusion Maranon has selected the paraphrase critical age

Before entering into a description of this period of man's life it is necessary to point out certain essential differences that distinguish it from the corresponding age in a woman First it should be remembered that the female menopause is primarily a genital episode having secondary reactions on other systems and organs In the case of man the climacteric has a different significance Man's critical age is as Maranon has expressed it a stage of organic evolution in whose centre the extinction of active genital life stands out prominently although this is not the axis on which it turns As adolescence marks his passage from childhood to maturity so does the climacteric represent his descent from maturity to old age The biological foundation on which it rests is genital decadence and secondary neuro endocrine reactions

We need not be surprised that the climacteric is less noticeable and less defined an event in the life of man than in that of woman or that it is less closely linked with the extinction of the genital function Although reproduction is an act in which both male and female play a part that played by the female is immeasurably greater than the part allotted to the male Nature has expended all her ingenuity in fitting woman for her role as major partner in the work of carrying on the race Whilst in man other activities have been considered in woman she has allowed herself no latitude in her planning and has sacrificed everything to the end in view Whether it be pleasing or not to her political aspirations it is a fact that everything in woman is sacrificed to the reproductive function But she can at any rate console herself with this arrived at a certain age she is once and for all relieved of the chief disabilities from which she has previously suffered The menstrual cycle ceases the organs of reproduction involute and she can enjoy her rest For man on whom the task of reproduction places no burden this definite and sudden change is totally unnecessary Procreation is for him an activity that makes small demands on his resources, he can carry the burden of

A lecture delivered to the Sunderland Division of the British Medical Association November 1931

the reproductive function ever under its physical powers are on the wane. So it happens that involution of the reproductive system occurs at a later date in the male than in the female, and in certain exceptional cases may be postponed to ripe old age. In the majority of men however we find signs of involution beginning in the organs of generation during the later part of the fifth decade and the beginning of the sixth—the age of the Greek grand climacteric. The cause of the involution is imperfectly understood but as we know that the ovaries play an important part in the involution of the female genitalia so we can be certain that the testes exert a controlling influence on the involution of the reproductive system in man.

But testicular insufficiency is introduced with less abruptness than is the ovarian insufficiency that marks the female menopause. In the case of woman the ovaries pass from full activity to complete cessation of function in the course of a few months. In man the process of genital extinction may be spread over several years. As a result the increase in thyroid activity which characterizes the female menopause is less marked in the case of the male. The disturbance of his endocrine balance is gradual rather than sudden and he is exempt from the violent flushings of heat, the palpitations and the tachycardia that so commonly reveal thyroid dysfunction in the female. When hyperthyroidism occurs in the man it usually reveals itself only in a gradual loss of weight and in a mild degree of psychic irritability.

The menopause is a physiological process and in the perfectly healthy female is accompanied by only two symptoms, the cessation of the menstrual flow and the occurrence of certain vasomotor crises commonly known as flushings. Unfortunately there are comparatively few individuals who can be regarded as perfectly healthy and more often than not the menopause is associated with various symptoms of ill-health. Not only is it a period of endocrine instability but we find that just as constitutional weaknesses tend to manifest themselves at the time of adolescence so do they show a disposition to return at the period of involution. Moreover the work of involution of the reproductive system is not always accomplished without the occurrence of some accident. For example we find that in the female such diseases of the breast as menstrual mastitis, mammary cysts and neoplasms are particularly likely to develop at this time. Later I will describe some of the accidents that are likely to occur during the process of involution of the male reproductive system. First however it will be convenient to consider certain changes of a constitutional character that occur at the time of his climacteric.

Changes in External Appearance

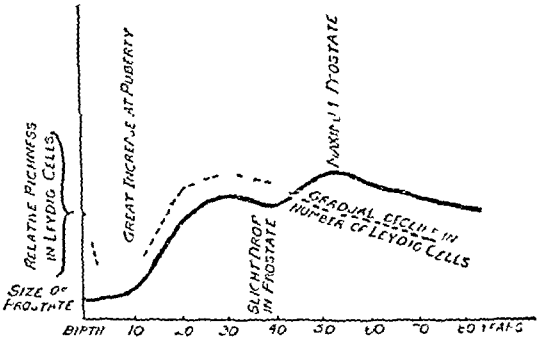
Just as the woman who has passed the menopause tends to put on weight and assume the rounded curves of the matron so does the man at the time of his climacteric show a disposition to become fat. It is not so much that he becomes generally obese but that he accumulates fat both within and on the walls of the abdomen. Indeed abdominal adiposity may be seen in a man who otherwise remains thin. When this accumulation of fat is excessive various minor disturbances of health may be produced. Circulatory embarrassment is the commonest. The patient because he feels short of breath after exertion stops all exercise and muscles still more rapidly in the direction of old age. Next to the circulation the digestion is most prone to suffer. Flatulent dyspepsia is a common sequel and with the increase in intra-abdominal pressure due to his meteorism there is produced a further embarrassment of the circulation. The patient catches up in this vicious circle of his abdomen resigns himself to his armchair and his newspaper.

Another result of this tendency to abdominal adiposity is a inability to develop exercise. Increased abdominal pressure and weakening of the abdominal walls produce just the conditions which are necessary for this and it is to the male climacteric that the truss makers owe half of their business. Even when no bulging can be detected in the region of the inguinal canals symptoms may occur which point to an equal weakness in a stretching of muscles. Not infrequently a patient whose abdominal walls have suffered as a result of his progressive and underexercise will complain of a pain that is only relieved by lying down. His trouble can be dealt with by the use of a light truss or a well-padded belt. But in many cases the change in external appearance may be towards thinness rather than fat. Certain women who have struggled up to the time of the menopause with a disposition to put on weight find that at last they can eat what they like without any anxiety about their figure. So too in rare cases men who show that they have reached the climacteric by a loss of mass. The reason is the same in both sexes—overaction of the thyroid.

While an alteration in weight is a common feature of the climacteric it can by no means be regarded as essential. A man may conserve his figure and maintain his weight and only when his friends look at him through some subtle difference which they find difficult to put into words. He looks older, they say, and by this they imply that he has moved not gradually but suddenly in the direction of old age. In this his friends are right, for it is an undoubted fact that our progress through life is not so much a steady continuous movement, as a motion which can best be described as a series of jerks. The boy suddenly becomes a child, the child an adolescent, the adolescent a man, and in the downward course the mature man passes quickly into the climacteric and finally, if he survives it, he is plunged into senility. As physical science has found that changes in the orbit of the electrons occur in jumps and so suggested that variations appear suddenly as sports, we doctors should realize that our journey through life is by a series of abrupt steps rather than by an even progress from the cradle to the armchair. Perhaps when we understand better the laws under which we live we shall discover some basic rhythm underlying these changes, but in the meantime we must be content meekly to record as did that greatest of observers Shakespeare when he gave us his classical description of the seven ages of man. But the upset of the endocrine balance and the metabolic changes marking the climacteric do not reveal themselves only in an alteration of external appearance. There are sometimes more definite disorders in a change in the patient's character. These psychological features of the climacteric will now be discussed.

Changes in Psychology

In man's social relations and in his business or professional activities two opposing sets of forces may be said to be at work—the native of ambition and the passion of combat. In youth the former predominates, for youth is characterized by its submission to impulse, its disregard for consequences, its lack of self-criticism and its fondness for the new adventure. These are the forces that lead to great discoveries in art and science and to achievements in general. With advancing age these active forces play a progressively smaller part in the life of the individual while inhibitions prevail increasingly. The work of a man who has reached the climacteric is stripped of the audacities and aggressive character of youth and he moves in the direction of conservatism. This is the normal course of mental evolution but as exceptions to this general law we find many examples of artists statesmen and scientists who have accomplished their best



and most revolutionary work after the age of 50 What is of great interest from the standpoint of this paper is the fact that almost without exception these unusual men who have retained their power to innovate have also retained their sexual activity

But just as we find few women who pass through the climacteric without giving evidence of some emotional disturbance so there are few men in whose psychology the endocrine readjustments of the period are not reflected As a rule this shows itself in nothing more marked than a certain degree of emotional instability, but in certain cases greater deviations from the normal may appear Not infrequently these disturbances have a sexual character The critical age is often associated with a sudden flare up in the dying embers of desire Novelists have made good copy out of the dangerous age in woman In man the corresponding phenomenon has because in general it is less marked received little attention As a rule it is productive of nothing more sensational than a conflict between desire and the capacity to achieve—a conflict that may in some cases be the starting point of a neurosis But sometimes this increase of sexual urge has graver consequences especially when it takes a somewhat abnormal form The most frequent of these abnormal forms is what has been termed the gerocomic tendency '—that is the desire of an elderly man for very young girls At times this urge reaches an intensity that is definitely pathological and brings the victim into conflict with the law It must surely be apparent to the most unimaginative of magistrates that the eminent and elderly gentleman arrested in Hyde Park for indecent behaviour should be treated as an invalid rather than as a criminal A man who has led a highly respectable life for sixty years does not suddenly run counter to all his habits and indulge in indecency unless he is the victim of a compulsion that is stronger than his will His exhibitionism is as certainly the psychological consequence of an upset of the endocrine balance as is the sudden infatuation of a woman in the mid forties for a youth of half her age It is possible that he may always have harboured certain latent and unsatisfied fantasies but it is the neuro endocrine instability of the climacteric in its excitable phase that has resulted in his surrender to what had previously been inhibited Fortunately these manifestations of a disordered psychology are comparatively rare and in the majority of instances the change in mentality associated with the climacteric is reflected in nothing more serious than say a disposition on the part of a previously cautious business man to gamble or in an alteration in the character of pictures that an artist paints or novels that a novelist writes Interesting as these speculations are it is with the local manifestations of involution rather than with the constitutional and psychological that I as a genito-urinary surgeon am chiefly concerned and with these local changes I shall now deal

Changes in the Reproductive System

Of [illegible] importance on account of the difficulties it [illegible] possible to talk otherwise than the changes that affect us not a new one for long was first drawn to the idea wrote of the grand climacteric years ago when I was the age of 63 In medical literature the causes and nature of age for man has also found a place although was struck by the authorities as Kraft Ebbing and Vinay have sections of an there is any psychological evidence to support the process of was to the term male menopause that I distension of was chiefly opposed and as Gregorio Marañon the formation excellent work on the climacteric such an I found that menopause implies an initial error By impressed by this phrase is meant a cessation of the menst it in some of his prostatic enlargement there are to be found signs of regression and degeneration not only in the prostate but also in the whole of the genital tract, more especially in the testes and the seminal vesicles The changes in the prostate are only part of a general involutionary process affecting the whole of the reproductive system But even if we are right in regarding enlargement as an accident occurring during the course of prostatic involution, we are still faced with the difficulty of explaining this accident Why does one prostate undergo shrinkage after active sexual life has ceased, whilst another not only fails to shrink but actually enlarges?

If we examine the prostate at various periods throughout life we find that it increases in size up to the age of 30 and then, diminishing slightly reaches its maximum between 50 and 60 After this, in a healthy man who has passed satisfactorily through the ' menopause it falls steadily so that in old age it has shrunk to perhaps half its previous size The following figure shows graphically the changes in the prostate from childhood to old age

The curve has been constructed from Lowsley's paper dealing with the *average* weight of the prostate at different times of life so that it includes the normal with the pathological We are ignorant of the factors that determine whether or not a gland undergoes successful involution Ciechanowsky believed that there was no actual increase of glandular tissue in cases of enlargement but that the swelling resulted from obstruction in the prostatic ducts causing distension of the acini It is certainly true that the enlarged prostate is full of distended glands for if we incise it a milky opalescent fluid exudes and a microscopical section of the gland reveals the presence of many distended acini Whether this alone will explain enlargement I am doubtful and I have at any rate never been able to establish any relationship between the size of the prostate and the degree of distension of the glands But overloading of the glands with secretion certainly plays a part in enlargement and it is probably on this account that prostatic *massage* frequently relieves the symptoms in early cases of obstruction

Ciechanowsky considered that the occlusion of the prostatic tubules was the result of surrounding inflammation followed by fibrosis and subsequent contraction If the inflammation is in the neighbourhood of the ducts, the result will be distension of the acini and general enlargement of the gland On the other hand if it is situated in the neighbourhood of the acini general shrinkage takes place with the production of a small fibrous prostate But from my own personal observations although I have found a clear connexion between previous attacks of inflammation and the production of a fibrous prostate I have never been able to establish any relationship between an enlarged gland and a history of old infections For this reason I am unable to accept Ciechanowsky's inflammatory theory as a satisfactory explanation of the etiology of enlargement Even less

* A lecture delivered to the Sunderland Division of the British Medical Association November 1931

can be found to support other theories that have advanced such as that enlargement is the result of sexual excesses or sexual starvation or that it is in the nature of a compensatory hypertrophy The same is true of the observation that prostatic enlargement is a disease which has a definite geographical or to be more exact ethnographical distribution If we could explain why it is so exceedingly rare amongst Mongolians we should be in possession of a valuable key to its etiology

Accidents Affecting the Testicle

Next to the prostate the part of the genital tract that is most likely to suffer during the course of involution is the testicle It is during this period of life that hydroceles are particularly liable to develop Such hydroceles have up to the present been termed idiopathic since no satisfactory explanation of their etiology can be given In my opinion a better term would be degenerative as they are almost always secondary to degeneration in the testicle itself It has of course long been recognized that the testicle associated with a hydrocele in elderly men is often hard and a microscopical examination of the gland invariably reveals fibrosis associated with degenerative changes in the tubules and ducts These changes are patchy in distribution that is to say one finds areas that are comparatively normal and adjoining areas where the epithelial cells are degenerating or have even disappeared When we consider the testicle rather than its coverings we find that the epididymis is more likely to suffer during this period of involution Clinically this is shown by the development of multiple retention cysts due to stenosis of the epididymal canal and vasa efferentia from the contraction of surrounding fibrous tissue Mr Ogier Ward states that in a study of cases of multiple epididymal cysts he found the average age at which they occurred was 55 a fact which in my opinion points to their being degenerative phenomena They may indeed be considered analogous to the cysts so commonly found in the ovary at the time of the menopause As a rule they cause only a trifling discomfort to the patient but since they result in an increase in size of the testicle they are not infrequently the cause of unnecessary anxiety The simplest method of treatment if treatment be required is tapping but if this only produces temporary relief excision may be carried out

Although the seminal vesicles show marked signs of degeneration in cases of prostatic enlargement any symptoms for which they may be responsible are so often complicated with and overshadowed by the symptoms resulting from prostatic disease that they are negligible Sometimes as a result of obstruction in the ejaculatory ducts the vesicles become distended or pouched and subsequently more dilated and are often the site of a chronic inflammation Occasionally a stone is formed from the deposition of lime salts round a nucleus of epithelial cells and spermatozoa These calculi or concretions may give rise to such symptoms as pain in the pelvis ejaculation pain on defaecation and haematuria Their chief importance however is in the fact that they may be mistaken for malignant disease and thus lead to an error in diagnosis

Treatment of Disturbances at the Climacteric

The treatment of the male climacteric consists in dealing separately with the various disturbances to which it gives rise In the case of a woman it is otherwise for not only is her menopause definite in character but we are fortunate in possessing various extracts of a [illegible] etic nature It is doubtful whether even if we possessed them similar benefits would result from the use of particular extracts in man I have observed no [illegible] after attempts to increase the supply of testicular [illegible] by tying the vasa nor have such bland efforts as [illegible] therapy as the giving of prostatic extract to cases of enlargement borne any fruits If not nothing I have seen leads me to believe either that the prostate has any internal secretion of its own or that its enlargement is associated directly with changes in any of the endocrine hierarchy other than the testis Until therefore we understand more fully the factors responsible for prostatic enlargement and until we are able to postpone in man the arrival of his critical age we shall be compelled to deal with the various accidents that accompany it by the crude but nevertheless successful methods of the surgeon

OTITIC HYDROCEPHALUS A REPORT OF THREE CASES

BY

C. P. SYMONDS M.D. F.R.C.P.

PHYSICIAN FOR NERVOUS DISEASES GUY'S HOSPITAL ASSISTANT PHYSICIAN NATIONAL HOSPITAL FOR PARALYSIS AND EPILEPSY CONSULTING PHYSICIAN TO THE LONDON FEVER HOSPITAL

In each of the following cases the clinical evidence suggested up to a point the presence of a cerebral abscess secondary to otitis media The question at issue when the patients were first seen by me was whether an exploratory operation should be undertaken In all cases the application of certain criteria led to the diagnosis of otitic hydrocephalus symptoms of increased intracranial pressure were relieved by lumbar puncture and the patient made a complete recovery

Of the pathological basis of otitic hydrocephalus we have no precise knowledge It is a condition in which otitis media—with or without such complications as a preliminary meningitis extradural abscess or lateral sinus thrombosis—is associated with an excess of normal cerebro-spinal fluid under excessive pressure The clinical symptoms are those of increased intracranial pressure—headache vomiting and papilloedema—and in this respect are similar to those caused by a cerebral abscess There are however certain points of clinical distinction between the symptoms of otitic hydrocephalus and cerebral abscess upon which the differential diagnosis may provisionally be made at the bedside When this stage has been reached the diagnosis must be confirmed by appropriate investigation of the cerebro-spinal fluid The main points of clinical importance are as follows

1. The most striking feature of otitic hydrocephalus is swelling of the optic discs This with haemorrhage and exudate frequently amounts to several dioptres In cerebral or cerebellar abscess on the other hand the optic discs commonly show no more than a slight venous engargement Such a degree of swelling as is met with in otitic hydrocephalus is rarely seen in a case of abscess and is then usually accompanied by extreme drowsiness

2. In striking contrast to the appearance and symptoms in otitic hydrocephalus is the general appearance of the patient the deformity of Bezold as the seat of origin and as painless as a [illegible] and [illegible] The patient then comes under observation [illegible] loss of function consequent to the deformity The condition may be considered as a feature of the [illegible] which has ended in faulty alignment and this faulty alignment has altered the arc

3 The common situations for abscesses are temporal and cerebellar By the time symptoms of increased intracranial pressure are evident, a cerebellar abscess will have given rise to definite localizing signs, of which the most important are nystagmus towards the site of the abscess, and incoordination in the use of the upper limb on the same side A left temporal abscess also (in the case of a right handed person) will almost certainly have produced localizing signs in the form of word forgetfulness Weakness of the opposite face and a homonymous defect in the opposite visual field are also signs of localizing value in temporal lobe abscess A right temporal abscess however is relatively silent and the differential diagnosis from otitic hydrocephalus is more difficult

If on the basis of these clinical points of distinction the condition of hydrocephalus is suspected, lumbar puncture should be done a manometer such as Greenfield's being employed The characteristic features in hydrocephalus are a high pressure and a normal fluid—that is *no* excess of cells or protein Fluid from a case of cerebral abscess is also likely to show a high pressure but this is not so high as in hydrocephalus Taking the average normal pressure as 150 mm H O, the pressure in abscess may be from normal up to 250 while in hydrocephalus it is more commonly in the neighbourhood of 300 Finally so far as I am aware the fluid in a case of cerebral abscess is never normal Usually there is a small excess of cells (mainly lymphocytes with a few polymorphs), always there is an excess of protein

The diagnosis being settled by these means the condition of otitic hydrocephalus will clear up if treated by lumbar puncture Enough fluid should be removed on each occasion to bring the pressure to normal and the procedure should be repeated so long as evidence (symptomatic or manometric) of increased pressure persists Any local condition such as mastoiditis or lateral sinus infection should be treated on its own merits but the existence of hydrocephalus is not in itself an indication for operative intervention The conclusions thus stated were reported more fully in a paper by the writer in *Brain*[1] of this year The cases now to be related have been encountered since that time

CASE I

Doris S aged 5 Under the care of Mr T B Layton Guy's Hospital Seen September 13th 1931

The patient was admitted with symptoms of right sided mastoid infection three weeks ago Mr Layton operated next day and found dense bone with a bead of pus in front of the lateral sinus At this time some neck stiffness was noted but disappeared later The temperature settled down but has gradually risen again There has been a good deal of complaint of frontal headache Yesterday the patient had a rigor

Examination—Child alert fretful but later co operated excellently Right handed No speech defect Optic disks show papilloedema 4 dioptres on right 1 dioptre on left Visual fields—full to rough tests Cranial nerves—no defect No incoordination or weakness Deep reflexes—present Abdominal—present and equal Plantar responses—flexor No [illegible] stiffness Heart and chest—normal

Provisional Diagnosis—Lateral sinus thrombosis and otitic hydrocephalus

Lumbar Puncture—Clear fluid Pressure between 250 and [illegible] is not wrote of [illegible] H O Examination No cells Protein 0 02 per [illegible] the age of 65 [illegible] eration the same day showed lateral sinus thrombosis dealt with [illegible] age for man has [illegible] 931—Papilloedema subsiding Child better authorities as Kraft [illegible] [illegible]—Condition excellent Temperature there is any psychological Papilloedema [illegible] Pre right was to the term male menopause recovery complete distens was chiefly opposed and as Gregor [illegible] no the formation excellent work on the climacteric such an I found that menopause implies an initial error By depressed by this phrase is meant a cessation of the menstrual in some of his [illegible] that in cases of

* A lecture delivered to the Sunderland Division of the British Medical Association November 1931

May 21st 1931 Mastoid operation by Mr Layton Extensive bony disease Dura and lateral sinus normal May 24th 1931 Sudden rise of temperature to 104° Further operation showed lateral sinus partially thrombosed Jugular vein tied Anti streptococcal serum given Subsequently temperature gradually subsided and after June 15th 1931 remained normal General condition good but patient complained of severe bifrontal headache on waking in the morning and of failing vision

June 24th 1931—Mentally clear Speech normal Optic disks—4 dioptres of papilloedema right and left with haemorrhages and exudate Visual fields—full Cranial nerves—slight weakness of peripheral type right face (ascribed to operation) No other defect No weakness or incoordination Deep reflexes—present and equal Abdominals—present and equal Plantar responses—flexor

Provisional Diagnosis—Otitic hydrocephalus

Lumbar Puncture—Clear fluid Pressure 312 mm H O Examination No cells Protein 0 02 per cent Further lumbar punctures were done at increasing intervals of time until the pressure became normal

July 11th 1931—Papilloedema less Occasional slight headache Left hospital later recovered

CASE III

Winifred B aged 18 Under the care of Mr Nicol Rankin Central London Throat Nose and Ear Hospital Seen March 12th 1931

History—Admitted February 24th 1931 with a story of right otorrhoea for two months and complaint of headache for the past week with vomiting after every meal Tender area over right mastoid antrum February 25th 1931 Operation by Mr Rankin—right Schwarzte mastoid operation March 10th 1931 Rigor followed by rise in temperature Right sided tinnitus and occasional twitching right side of face

March 12th 1931—Mentally clear and co operative Speech normal Right handed Optic disks—papilloedema 5 dioptres right and left with haemorrhages and exudate Visual fields—full to rough tests Cranial nerves—nystagmus elicited on conjugate deviation to left Slight weakness right orbicularis palpebrarum Other cranial nerves normal No weakness or incoordination All deep reflexes present and equal Abdominals—present and equal Plantar responses—flexor No neck stiffness No signs elsewhere

Provisional Diagnosis—Otitic hydrocephalus associated with lateral sinus thrombosis and labyrinthitis

Operation by Mr Rankin the same day revealed lateral sinus thrombosis which was dealt with

Lumbar Puncture—Clear fluid Pressure not measured Examination No increase of cells or protein

The patient made an uninterrupted recovery and was reported by Mr Rankin on May 3rd as perfectly well

There are two points in the story of these cases which deserve further comment One is the occurrence in all three of lateral sinus thrombosis It has been suggested by Leidler arguing from the experience of a single case in which the same association was observed, that hydrocephalus may result from lateral sinus thrombosis on account of obstruction to the venous outflow from the cranium Against this hypothesis it may be said that if it were true hydrocephalus should be a frequent instead of a rare accompaniment of venous thrombosis Moreover among the cases of otitic hydrocephalus that have so far been published there have been several in which no evidence of lateral sinus thrombosis has been present The second point of interest is the age in the second case described above It would appear from the cases so far recorded that otitic hydrocephalus is rarely met with in adults

prosta[illegible] thanks are due to Mr T B Layton and Mr Nicol relatio[illegible] for inviting me to see their patients and for permission old in[illegible]

TREATMENT OF ADOLESCENT COXA VARA*

BY

GEORGE PERKINS, *M.C.*, M.Ch., F.R.C.S.

ASSISTANT ORTHOPAEDIC SURGEON TO ST. THOMAS'S HOSPITAL.

Adolescent coxa vara needs little introduction to this Section. Briefly, it is a condition arising about puberty in girls and boys in which from some unknown cause the head of the femur becomes separated from the neck of the femur. This separation takes place at the epiphyseal line and is thus different from the so-called displacement of an epiphysis due to trauma in which the line of cleavage does not entirely follow the epiphyseal line but passes for some distance through the metaphysis. This separation may be complete or incomplete and may occur rapidly or gradually causing a variety of clinical types demanding a variety of treatments. We may consider the following types:

MINOR INCOMPLETE SLIPPING

With strenuous use of the hip-joint—for example during a game or a romp—the epiphysis may slip just a trifle. The patient has some pain and a limp. These symptoms may be transient, lasting a day or two, and insufficient to bring the patient under the observation of a doctor. If however the doctor does make an examination he finds at the hip-joint some limitation of movement in all directions and would diagnose the condition as a sprain of the joint but for the radiogram. The radiogram reveals the diagnosis a fact which emphasizes the importance of taking a radiogram after every suspected injury and of comparing the damaged joint with that of the opposite side. This incomplete separation it is impossible to reduce, nor is reduction necessary, as the slight anatomical abnormality gives rise to no disability. Treatment consists in resting the hip-joint until the head of the femur has become firmly re-attached to the neck. It goes without saying that this treatment must be efficient, and if a crutch is placed on the weight-relieving calliper care should be taken that weight is indeed relieved.

RECURRENT INCOMPLETE SLIPPINGS

The original slipping may be neglected by the patient or its importance may not be appreciated by the doctor. The patient resumes his normal life and may have no further trouble. There may however be a recurrence of symptoms and after several such the x-ray change becomes unmistakable. This displacement is incomplete and it is not possible by manipulation to reduce an incomplete displacement. I repeat this statement for emphasis and to challenge contradiction. It is not possible by manipulation to reduce an incomplete displacement, for although a considerable force can be exerted on the neck fragment with the leg the capital fragment can not meanwhile be held immobile and the force is expended on the capsule of the hip-joint and not on the epiphyseal line. This is an important fact and its lack of appreciation accounts in part for much faulty treatment. It is true that under anæsthesia it is possible to actually to rotate the leg fully and to abduct the leg fully, but only at the expense of damaging the capsule and with subsequent loss of movement at the hip-joint. This accounts for the paradoxical statement based on follow-up reports that untreated cases of adolescent slipped epiphysis do better than treated cases.

Treatment for an incomplete slipping should therefore be to rest the hip-joint until the head and neck have become firmly re-united in their new position. Then if the epiphyseal coxa vara deformity due to the malunion between the head and the neck warrants an osteotomy of the femur, so it should be undertaken. Attempts have been made by surgeons who have recognized the impossibility of reduction by manipulation to reduce the displacement at open operation by osteotomizing the neck close to the epiphyseal line after exposing the hip-joint and opening the capsule. Wilson of Boston advocated this. We have done it once; the result was complete destruction of the joint following an aseptic necrosis of the head of the femur. The necrosis was solely due to the surgical intervention, but whether preventable or not I do not know. This one experience has precluded for us a further trial of the method.

RAPID COMPLETE SLIPPING

It sometimes happens that the separation takes place rapidly and is complete. The symptoms then resemble those of a fracture of the neck of the femur and immediate complete loss of function is usual. In this type closed reduction is possible and is the correct treatment. The closed reduction may be done gradually or rapidly. The rapid method is associated with the name of Whitman. Under anæsthesia traction is exerted on the leg to pull it down, then the leg is forcibly internally rotated and finally adducted, and is held by a plaster spica in that position. My own preference is for the gradual method of reduction by means of prolonged traction on the leg, and I prefer skeletal traction to skin traction. A Kirschner wire or a Steinmann pin is inserted through the ankle of the femur, two cords extending from it run over pulleys fixed to the end of the bed, and are attached to 20 to weights. Counter-traction is by body weight, the foot end of the bed being raised 12 in. or more. This method is simple to apply even in a private house. The hip is not held rigidly immobile, and the muscles of the knee and the ankle can be exercised gently to prevent stiffness at those joints. The leg may be cradled in a Thomas knee splint, but that is a refinement. The traction is sufficient of itself to reduce the displacement; no additional and complicated splinting is necessary to overcome the adduction and external rotation of the leg.

Apart from its simplicity the gradual traction method of treatment has another and more important advantage. I have stated that if the slipping is gradual no method of reduction is of avail, but that if the slipping is rapid and complete reduction should be attempted. Now while as a rule it is possible to diagnose without hesitation every patient to one or other of these groups difficulty sometimes arises and one is uncertain whether reduction should be attempted or not. In such a quandary the gradual traction method has the advantage that any movement of reduction can be made which even if a fracture will not damage the hip-joint. Several times I have sent for an x-ray photograph at the end of that time will show whether the pull is taking place at the line of separation between the head and neck or is being exerted solely on the capsule. If reduction is not taking place the traction is discontinued and the patient treated as in Type 2 (incomplete slipping).

COXA VARA: THE RESULT OF SLIPPING

The slipping may be so gradual that at no time gives rise to symptoms and there develops the deformity of coxa vara as it does in its origin and as painless perhaps as genu valgum. The patient then comes under observation for the loss of function consequent to the deformity. The condition may be considered as a fracture of the cervical neck which has united in faulty alignment and this faulty alignment has altered the arc

* [illegible] Annual Meeting of the British Medical Association, London, 1931.

of movement at the hip joint—that is increasing the external rotation and adduction and diminishing (even abolishing altogether) internal rotation and abduction Should the diminution in abduction and in internal rotation be sufficient to cause disability, then the arc of movement at the hip joint can be restored to its normal by a subtrochanteric osteotomy of the femur—that is the malunion at the junction of the neck and head, brought about by nature can be counterbalanced by a second malunion of the femur in its upper third brought about by the surgeon

In this group come not only those patients who present themselves with a coxa vara without previous symptoms but also those patients seen at or soon after the occurrence of slipping and in whom closed reduction by gradual traction has failed or has been deemed inadvisable

Persistent Arthritis of the Hip Joint

Yet a final group remains in which persistent arthritis of the hip follows a slipping of the epiphysis In these patients one assumes that the blood supply of the head has been permanently damaged so that the head of the femur undergoes partial or complete necrosis We are familiar with this in the case of a transcervical fracture of the neck of the femur in which it happens more commonly because the blood channels in the ligamentum teres are more likely to be still patent in the adolescent than in the adult Complete separation of the epiphysis must one argues cause necrosis of the head unless the ligamentum teres vessels are still patent and escape damage The importance of preserving this remaining source of blood supply is a further argument in favour of the gradual method of reduction in preference to the rapid I have said that persistent arthritis of the hip may follow a slipping of the epiphysis Perhaps it would be more correct to say that it may be the sequel to a slipped epiphysis that has been treated for it is just as likely that the remaining vascular supply to the isolated head is damaged by the forcible manhandling of the limb by the surgeon at the attempt at its reduction as that the damage is done at the time of the slipping The slipping can only destroy the blood supply originating from the neck the forced manipulations of the surgeon may destroy in addition the vessels of the ligamentum teres

Persistent arthritis of the hip is easy to recognize clinically and the x ray photograph shows in old slipped epiphysis with consolidation between the epiphysis and the displaced head diminution of the joint space and increasing deformity and destruction of the head of the femur Arthrodesis of the hip joint is recommended as the best treatment

Summary

Treatment for a slipping of the upper epiphysis of the femur may be summed up as follows

1 When the slipping is gradual and incomplete relief of weight bearing must be maintained until the new position has been consolidated

2 When the slipping is rapid and complete gradual correction should be done by skeletal traction followed by relief of weight bearing until the new position is consolidated

3 When the sequel to the consolidation in the new position is an alteration in the arc of movement at the hip leading to loss of function a subtrochanteric osteotomy is necessary

4 When the sequel is a persistent arthritis of the hip, the hip joint should be arthrodesed

A CASE OF BRACHIAL EMBOLECTOMY

BY

A GRAY BANKS M D LRCS ED

SURGEON EAST SUFFOLK AND IPSWICH HOSPITAL

A general labourer aged 66 was admitted to the East Suffolk and Ipswich Hospital with a double hydrocele His cardiovascular condition previous to operation was noted as unsatisfactory The apex beat was in the sixth interspace outside the nipple line, a soft systolic mitral murmur and occasional extrasystoles were present at the aortic area a systolic murmur and prolonged second sound Marked arteriosclerosis Corrigan pulse Blood pressure systolic 220 diastolic 85 The patient said he had been under treatment for heart trouble several years before but had not noticed anything wrong lately beyond slight shortness of breath although his work was strenuous

Radical operations were done under spinal anaesthesia On the morning of the ninth day he complained of numbness and loss of power in the right forearm and hand with pain just above the bend of the elbow The hand and distal two thirds of the forearm were pale and cold, with a dusky ring of injected capillaries at the upper end The radial pulse was absent but normal pulsation could be felt in the brachial artery just above the elbow

Operation.—Under local anaesthesia a four-inch incision ending at the elbow crease was made along the line of the artery, and the vessel gently mobilized two small lateral branches being carefully preserved A light intestinal clamp was placed on the artery two inches above the bifurcation and an opening one centimetre long was made one inch above the latter There was no flow *from the lower end* A *pair of fine curved sinus forceps* was passed down into the distal end and an embolus three quarters of an inch long with rounded ends was fished up A little leakage then occurred from the lower end of the vessel which was gently milked upwards in case any further clot were present although this seemed unlikely from the character of the embolus and the short time elapsing between onset and operation The artery was sutured with fine thread soaked in liquid paraffin interrupted sutures piercing all the coats were used On releasing the clamp excellent pulsation was immediately felt in the radial at the wrist and under the suture line During the operation the parts were soaked with 1 per cent citrate solution from time to time The wound was closed with one layer of silkworm gut sutures in the usual way and a light splint applied to immobilize the elbow, the hand being left free

The radial pulse remained full and regular and the arm warm and of normal colour The splint was removed in a few days and the elbow gently moved only after the tenth day When seen two months later the hand and arm were normal and pulsation could be clearly felt along the whole of the exposed length of artery Beyond a little shortness of breath his heart was not giving any trouble and he was doing his ordinary work

Some General Remarks

Arterial emboli are less common in the upper than in the lower extremity fewer than half of the recorded cases being axillo brachial In Danzis's collected series of twenty eight embolectomies five were brachial and five axillary The proportion is much the same in a series of cases published by Emrik Key - to whom and his Swedish colleagues we owe the pioneer work on this subject Two interesting cases of brachial embolectomy are described by Lerman Miller and Lund[2] illustrating some special points in connexion with this operation in the arm

Jeffe on's case was the first published in England and [illegible] of persist. He draws attention to the causative role of heart disease in the recorded cases. But C. Ollo estimates that in 80 per cent. of all cases there is a diseased heart the aortic valve being the usual source of the embolus. These emboli are often multiple necessitating more frequent surgical operations.

In placing the site of the embolus it is well to remember that it tends to lodge either at the bifurcation of the brachial artery or at the junction of a large branch—for example the profunda—with the main trunk. The exact site of the initial pain is a very important guide. Occasionally a lump may be felt in the course of the artery at the end of the pulsating area.

The general operative technique follows the usual lines of arterial surgery. The operation is best done under infiltration anæsthesia. The utmost gentleness in manipulation and the careful preservation of any small branches are essential. The wound is kept moist with 1 per cent. citrate solution to prevent coagulation. If the embolism is at the bifurcation the incision in the artery (which need not be more than one centimetre long) must be made above the embolus if thought to be at the junction of the profunda branch the incision would be placed below it and the embolus and any clot extracted distally. It may become awkward on releasing the clamp or it may require to be milked out or extracted with forceps. In a late case secondary thrombosis may be extensive and the radial artery difficult to clear. In one such case the radial at the wrist was opened a cannula inserted and the vessel flushed through with a syringe and 2 per cent. citrate solution. A continuous suture is probably better than interrupted sutures but in a small artery like the brachial more labile tension or [illegible] gaping is observed. Fine silk or thread is the ideal suture.

Prognosis

As regards prognosis the time element is the crucial factor. Key states that three-quarters of all brachial or axillary emboli dealt with operated on within two hours of onset. Early operation means less secondary thrombosis. In bifurcation emboli the arm should be immobilized in comfortable extension for a few days the hand being left free. The further outlook depends on the origin of the embolus or the grade of the heart disease. Secondary limb emboli have occurred in cases already successfully operated on for the same condition. A study of the literature shows as might be expected that the most favourable cases are those following operation and without grave heart disease the patient being still under observation—conditions ideal for early diagnosis and treatment.

[illegible] [illegible] [illegible] [

What is the cause of this arteriolar contraction? Diathesis psychic factors overwork sedentary occupations obesity endocrine changes circulating pressor bases have all had their advocates Their very number is a confession of our ignorance There is no doubt that high blood pressure is often familial Lord Dawson found a percentage of school children had pressures above the normal - but it is as yet too early to say whether any of them will eventually develop true hyperpiesia Nervous causes and overwork certainly raise the pressure but many men overwork and never suffer from hyperpiesia and neurotic people often have low pressures Sedentary occupations are blamed for many things hyperpiesia is only one of them Hyperpiesia and overweight may coexist but it is doubtful whether the majority of obese persons have high pressures There is no reason why circulating pressor bases should not be eliminated since it is known that the kidneys remain normal until their arterioles become affected with those of the rest of the body

Hyperpiesia will probably be found to be a deficiency disease As noted by Ismail[2] it has something in common with diabetes In both diseases the usual time of onset is in early middle age both run a prolonged course have a certain familial tendency and are frequently found together As in diabetes hyperpiesia is much more severe when it occurs in young people and its course is more rapid the so called malignant hypertension of Keith and Wagener[3]

A certain tension of the arterioles is necessary for everyone This tension is unlikely to be maintained by the sympathetic nervous system which is usually reserved for the rapid changes called for by the external environment By analogy with other systems of the body it is probable that a chemical agent is responsible It may well be that this substance or substances derived from protein, is normally present in excess and the fine adjustment is made by a hormone which converts it into something that can be excreted by the kidney This view would accord with the work of Bain[4] and Major[5] who have both found in normal urine substances with a pressor action these were absent or reduced in the urine of those suffering from high blood pressure If the hormone is inadequate the arterioles will be over stimulated and the blood pressure will have to be raised to maintain the circulation through the capillaries According to the extent of the hormone deficiency, various grades of hyperpiesia will result Overwork and worry are important secondary factors which will aggravate still further a state which is already abnormal

Whether this view is correct time will show Hyperpiesia is a malady for which we have at present no cure it will inevitably run its course The potential hyperpietic however demands active treatment to prevent if possible the condition becoming established In the later stages also much can be done to mitigate the disease both by countering the secondary factors of overwork and worry and by intensive courses aimed at relieving temporarily the stress upon the overburdened cardiovascular system

TREATMENT OF HYPERPIESIA*

BY

W EDGECOMBE M D, F R C P F R C S

PHYSICIAN HAYDOCK INFIRMARY

The treatment of hyperpiesia must be based on our conception of the cause and the mode of production of the disease Of the causes diathesis—the inherent often familial tendency to the affection—cannot be removed Psychical causes such as overwork anxiety mental stress and worry are more or less amenable to modification and must be remedied when possible Inactive metabolism accompanying obesity and sedentary occupations is susceptible to suitable treatment Endocrine factors—hyperadrenalism subthyroidism and disturbances of ovarian secretion as at the menopause—can be partially controlled though not with any great certainty except in the case of myxoedema Of the pressor bases concerned in the production of hyperpiesia we have little exact knowledge Believing them to arise in the alimentary canal and to be derived from protein we endeavour to control them by reducing the protein intake and by promoting active elimination of waste products by the bowel kidneys and skin Aperient and diuretic mineral waters and intestinal lavage by the *Plombieres* douches are valuable means to this end In illustration of the relation between intestinal infection and hyperpiesia the following two cases are of interest

CASE I

Male aged 49 when seen in 1913 had a blood pressure of 140 90 and was found on examination to have a large swelling in the region of the ascending colon which was diagnosed as a diverticulitis In January of the following year he was operated upon for suspected cancer of the bowel the growth was found inoperable, and the abdomen was closed In June his blood pressure was 145/95 In 1915 it had risen slightly to 150/95 in 1916 it was 160/100 reduced after a course of baths to 150/95 He was lost sight of until August 1923 when he reappeared with a blood pressure of 230/130 and symptoms of slight weakness and dragging of the left leg The swelling in the abdomen had almost disappeared but was still just palpable In seven years his blood pressure had risen from 160/100 to 230/130 A course of baths reduced it to 200/124 In 1924 his blood pressure was 220/125 reduced after a course to 200/105 and he died of cerebral haemorrhage in 1925 It is not unreasonable to infer that the chronic infection of the bowel was the cause of the hyperpiesia

CASE II

Male aged 48 in 1915 now aged 64 The records of his blood pressure date from 1916 and are seen to have gradually mounted year by year without any cause being discovered Each year he had a short course of spa treatment Between 1928 and 1929 there was a sharp rise for which no explanation could be found His blood pressure in May 1929 was 230/110 before and 180/110 after a course of baths In June 1929 he had an acute perforation of the bowel which was found on operation to be from a ruptured diverticulum He made a good recovery In December 1929 his blood pressure was 190/100 An x ray examination after a barium enema disclosed extensive diverticulitis of the large bowel Since then he has remained in good health

Consideration of the mode of production of hyperpiesia points the way to physical methods of treatment The primary fault lies in the peripheral circulation it is the narrowing of the arterioles and capillaries and the consequent diminution of the total channel area available to the blood stream that determines the high blood pressure the enlargement of the heart is a secondary resultant phenomenon Any measures that dilate the vessels and

Advanced cases require careful watching while under bath treatment If the pressure falls rapidly and considerably symptoms of lassitude, fatigue and breathlessness may supervene and the patient feels worse rather than better This is an indication that the reduced head of pressure is insufficient to maintain an adequate circulation that heart failure is impending and the treatment should be stopped at once If as the pressure falls, the heart rate slows or does not increase and the patient feels relieved all is well and the treatment may be continued A rise in heart rate with a fall in pressure is a danger sign Also a considerable fall in the systolic without a corresponding fall in diastolic pressure—that is a reduced pulse pressure—is an ominous sign of a failing left ventricle

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

CATARRHAL INFECTION AND FORMALIN VAPOUR

The prevalence of catarrhal conditions in schools especially during the early months of the year is I presume one of the main problems which confront every medical officer The loss of school time the overcrowding of the school sanatoriums and the strain imposed upon the nursing arrangements are harassing to masters and doctors alike I would suggest that systematic spraying punctiliously carried out on the plan laid down has a marked effect in cutting down the incidence of catarrhal conditions and in mitigating the virulence of the infection

Some four years ago with a badly infected boarding school of 140 boys it was decided that the school should be sprayed and a technique was evolved by the sister in charge (for which I can take little or no credit) which has been systematically carried out ever since The spray solution is 10 per cent formalin used in a sovereign metal spray The method which is as follows is carried out daily All class rooms and studies are sprayed including the tops of the desks the backs of all pews in the chapel, the heads of all the beds and spaces between the beds in the dormitories tooth mugs bathrooms corridors door handles and dining tables The spray which is a fine one is of course carried over a far larger area than the actual object on which it is directed The time taken over this work is about one and a half hours a day

I will now give the comparative figures of the numbers admitted to the sanatorium with catarrhal infection before and after this routine was established In this group of

Before Spraying		After Spraying	
Year	Admissions	Year	Admissions
1925	90	1929	30
1926	59	1930	15
1927	78	1931	31
3 years	227	3 years	76

The year 1928 has been omitted [illegible] beginning of the year and the [illegible] hyperpiesis not instituted at the standardized

infections I have included [illegible] influenza bronchitis and the pneumonias [illegible] excluded admissions from other causes

The figures tend rather to mislead in that one is far more prone to admit the slighter cases into the sanatorium when there is no pressure for space I have not given the number of days occupied in hospital for a similar reason—namely, that when there is little pressure the tendency is always to retain cases longer These figures are incomplete in a very important particular—that of the numbers who only attend the school surgery for the treatment of these conditions Such figures I do not possess, but their number is also stated to have been markedly reduced

There is no doubt in my mind nor in those of the sister and of the school authorities that the formalin spraying has been of very marked benefit Further, this improvement has coincided with the institution of spraying and has continued for too long a period to be a mere coincidence An interesting point is that for a short time the work was deputed by the sister to others Soon after an outbreak of colds and coughs started to spread through the school It was discovered that the work had been very perfunctorily carried out

I am less convinced of the efficiency of the spray in certain other infective conditions, such as follicular tonsillitis which would appear not to be controlled As to the exanthemata I am not in a position to express any definite opinion Their occurrences have only been slight during the period under review

In conclusion I would emphasize the apparent necessity for a punctilious routine and I should be delighted to receive information of the experience of others along similar lines

CLINICAL AND SCIENTIFIC PROCEEDINGS

NORTH EAST ULSTER DIVISION

Tuberculosis of the Abdominal Lymphatic Glands

At a meeting of the North East Ulster Division on December 11th 1931 with the chairman, Dr BOYLAN presiding Mr S T IRWIN M Ch F R C S read a paper on tuberculosis of the abdominal lymphatic glands

Mr Irwin discussed first the incidence of tuberculous infection and the arguments for and against the main portal of entry being the abdominal lymphatic glands He described the work of Calmette in this connexion and emphasized the importance of this probability as regards the diagnosis and prognosis in abdominal diseases In the category of acute emergencies, especially in childhood lymphadenitis occupied a prominent place but he was not sure that this term was quite satisfactory for all the types of this disease were not of definitely inflammatory origin and in many cases no palpable swelling was present Mr Irwin then submitted a comprehensive summary of the literature which indicated that these cases of lymphadenitis were due to the absorption of low grade infections caused not only by tubercle bacilli but also by other organisms

Anatomical investigations showed that the lymph vessels of the abdomen were grouped round the main arterial trunks with glands situated at intervals and that normally in all cases the largest glands in any group were placed proximally Three groups were of special pathological importance the one which accompanied the ileo colic artery and drained the lower six inches of the ileum the ileo caecal valve the caecum and the appendix the one surrounding the superior mesenteric artery and draining the jejunum and the upper part of the ileum and the group which converged upon the coeliac axis

and removed lymph from the stomach duodenum and gall bladder. The tubercle bacillus could pass through intact mucous membrane without leaving any trace but when ulcerous ulceration of the intestine occurred it would be found in 85 per cent. of cases in (1) the lower six inches of the ileum (2) in that part of the caecum which the stream of contents from the ileo-caecal valve impinged upon it (3) in the ileo-caecal valve itself. Mr Irwin remarked that the statement by Cameron—that enlargement of the hilar glands was much more common in the right pulmonary root than in the left while cervical enlargement was more common on the left side—might be correlated with the facts that the main thoracic duct began in the receptaculum chyli where it was situated on the right crus. It then ran up behind the root of the right lung and turned obliquely to the left opposite to the body of the fifth dorsal vertebra to enter the root of the neck on the left side where it joined the left innominate vein.

Mr Irwin then discussed the pathological changes in glands. He thought it could be argued that the route of infection in the superior mesenteric area was different from that in the ileo-caecal area. With gross glandular enlargement there developed abnormal irritability of the intestine so that even gentle handling of the gut produced spasmodic contractions especially of the circular muscle coat. These contractions tended to occur irregularly and were quite unlike the orderly passage of a normal peristaltic wave. The pain in these cases might be attributed to such contractions but Cornioley had suggested a vascular cause. Most of the glandular enlargements in the ileo-caecal area were of tuberculous origin the infection usually occurring in infancy or early life and the vehicle being milk. Although involvement of a single gland might follow ulceration of the small intestine it was much more usual to find a moderate but generalized glandular enlargement with the proximal glands more intensely affected. The cause might be and often was tuberculosis brought by the blood stream or it might be a *B. coli* or streptococcal infection referable to the appendix or the glands might be the seat of hyperplasia.

Such a survey of the anatomy and pathological variations of the mesenteric lymph glands as occurred with consideration of the nature and routes of infection led to the conclusion that a definite clinical entity was concerned although the symptomatology was diffuse and the findings at operation were manifold. Excluding cases in which a palpable lump could be detected and those in which intestinal obstruction was caused by adhesions or ulceration into the gut three classes of cases could be defined (1) those due to acute lymphadenitis of the ileo-caecal group seen during the acute stage (2) those due to chronic lymphadenitis subsequent to a previous acute attack and (3) those chronic glandular enlargements with no history of an acute attack. The first class closely simulated acute appendicitis and the differential diagnosis could only be made after a detailed history had been obtained and a thorough clinical examination had been carried out. Acute appendicitis especially in early life had in all these cases a glandular basis often gave a history of previous attacks of pain, tenderness and retching but the disease had occurred during one of the remissions and was associated with some degree of pyrexia. In glandular cases more often there was no consecutive set of symptoms as occurred when the appendix was first attacked and any perforation ruptured through a localized wall of inflammation to the peritoneal cavity. Mr Irwin thought that he had operated most often at night sided though Cameron had drawn attention to the sudden and generalized lasting pain in the epigastrium associated by prostration or heat and tenderness simulating abdominal. The pain in the appendix and the pain in the gland were similar and the pain in the gland was more and more. The superficial glands were usually enlarged but the mesenteric so. The adhesion was generally soft and easily broken down and the lymph nodes were the high right fossa as referred to the middle line as often was in early appendix cases. There was no limitation of the high movement. The progress was as a rule favourable and the disease was a self limiting one. No operation was usually necessary or desirable.

In the second group of cases (chronic lymphadenitis) there were frequent exacerbations with pain pyrexia and quick pulse. The infection was likely to spread and the glandular enlargement was generally unilateral but as a rule caseation or calcification would be found in some glands while others remained soft and fleshy. The enlargement might affect the ileo-caecal group alone or might be generalized involving the whole group also. Diagnosis in such cases was particularly difficult. The patient had gastric symptoms often including pain one to three hours after food with hyperacidity nausea loss of appetite and constipation. They were easily exhausted by overwork and confinement. They were almost invariably tender in the right iliac fossa though the tenderness was above and internal to McBurney's point. Test meal and radiological examinations might reveal high peracidity and delay in emptying the stomach. The patients were often thought to have the so-called lymphatic dyspepsia. The treatment was that of tuberculosis elsewhere with special attention to avoiding overfatigue and confinement.

The third group was less clearly defined. The symptoms were very vague suggesting at one time a disordered gall bladder at another a duodenal ulcer and sometimes a chronic appendicitis. Yet the clinical picture was at no time quite complete. There was no rise of pulse or temperature and various surgical procedures were tried in vain in case after case owing to the faulty diagnosis that were made. Mr Irwin had found about 275 such puzzling cases. 82 had been proved by operation to be cases of appendicitis 140 of duodenal ulcer and 53 of enlarged lymph glands. Much more histological and bacteriological investigation was necessary to clear up the etiological problem thus presented.

Reports of Societies

GYNAECOLOGICAL TUMOURS

At a meeting of the North of England Obstetrical and Gynaecological Society held in Liverpool on November 27th 1931 Professor Leslie Murphy showed a specimen of endothelioma of the ovary and all of the organs

The patient had had a history of pain and bleeding for three years. She had been operated on twice for fibroids of the uterus. Her complaint was of excessive pain and bleeding at the menopause. On examination a fungating growth was found on the anterior vaginal wall occupying the cervix. The uterus was adherent to the bladder and rectum. Removal was impossible. A piece was removed for microscopic examination and found to be a mucous Round cell sarcoma. Radium was applied to the growth. Subsequently the patient developed a vesico-vaginal fistula. The growth had not regressed and there had been a complete cessation of the bleeding. Section proved the tumour to be a typical adenocarcinoma. Sections through one of the lymph glands showed the squamous epithelium and pearl at the edge. This was not an infiltration and

Mr N L EDWARDS (Derby) showed an endometrioma in an abdominal scar following Caesarean section

The patient aged 33 had had a previous Caesarean section in 1923 In November 1929 Mr Edwards again delivered her by the same route through a left paramedian incision A portion of each tube was resected and the stumps buried and the right ovary being cystic was removed The scar discharged serum from the eleventh to the thirteenth day Recovery was afebrile Seen ten months later the patient said that she had noticed a black looking discharge from the upper end of the scar and that during the last seven periods there had been no pain A small purplish nodule was found at the point of the discharge with the uterus adherent to the anterior abdominal wall behind it This was confirmed when the nodule was excised two months later At the same time the abdomen was opened and the uterus was removed by subtotal hysterectomy along with the remaining ovary which was now cystic and adherent The nodule showed endometrial tissue but no connexion could be found between the endometrium of the nodule and the uterus

Of the two probable theories of origin—implantation during operation and metaplasia of peritoneal endothelium—Mr Edwards favoured the second in this case

Professor LEITH MURRAY described a dermoid cyst of the left ovary weighing over 29 lb and containing fatty balls and pellets

The patient a virgo intacta aged 52 had passed the menopause five years previously She had been aware of the tumour for fifteen years and at the time of operation the abdomen measured 73 inches at the level of the umbilicus A three inch incision was made in the abdomen and adhesions to the anterior abdominal wall were swept away with the hand Attempts at tapping having failed the cyst was incised and five and a half pints of greenish fluid containing several thousands of fatty pellets were evacuated These varied in size from a split pea to an almond but seven were found almost completely rounded and of much larger size The rest of the contents consisting of a fatty pultaceous putty like material was expressed through the incision the whole cyst being finally removed The inner and outer surfaces of the cyst wall were smooth and the only suggestion of a germinal node was a linear thickening about five inches long Examination showed this to be a channel lined by several layers of transitional epithelium with some suggestion of goblet cells There was also a narrow layer of involuntary muscle fibre The sebaceous glands discovered were mainly situated round this area as was also a hair follicle A ray examination was negative Some fine hairs were found in the fluid and in some of the balls examined An examination of the fatty material showed a large proportion of free fatty acid and non saponifiable matter which explained the fact that the fat was solid at body temperature

Dermoids of this type are extremely rare and Professor Leith Murray thought that by reason of its size the specimen was probably unique An account of previously reported cases was given and was followed by a highly technical and very full description of the various examinations of the specimen made by Mr Jeffcoate

Miss RUTH NICHOLSON showed an unusual tumour obstructing labour

The growth was removed seven months after the patient had been delivered by Caesarean section Previous to this she had had four normal labours On this occasion she was seen after she had been in labour for twenty eight hours with good pains The head was still high and a mass was felt in the pelvis to the right obstructing delivery A lower segment Caesarean section was performed by Mrs Dobbin Crawford during which the tumour was seen to be separate from the uterus lying on the right side of the pelvis and retroperitoneal about the size of a kidney The child's head showed marked moulding and a large caput At the second operation the tumour was found to lie between the layers of the right broad ligament and shelled out easily It had no connexion with the uterus It now measured 3 by 2 by 1½ inches and microscopically proved to be a fibromyoma with a preponderance of muscle elements

A case of chancre of the cervix was described by Mr J ST GEORGE WILSON

The patient, a multipara aged 48 complained of smarting and irritation of the vulva with a copious and occasionally blood stained offensive discharge of two months duration The cervix was enlarged and soft, and bled on palpation A diagnosis of carcinoma of the cervix was made and a piece of the growth removed for examination after which radium was applied Section showed lymphocytic infiltration and the Wassermann reaction was then found to be strongly positive

Mr Wilson said that the idea that chancres in this position were rare which he had previously held in common with the older writers, was proved to be erroneous by T A Davies of the St Thomas's Hospital venereal diseases clinic who showed the cervix to be the commonest site

Dr P MALPAS gave an interesting demonstration of the efficacy of gauze packing in maintaining radium containers *in situ* by means of a series of x ray photographs The films were taken, in each case, four and twenty two hours after insertion of the radium and showed no alteration The variety in the distribution of the containers according to the shape and extent of the growth was shown and it was suggested that a large number of different appliances would be required to meet every case

TREATMENT OF ANAEMIAS

At a meeting of the London Branch of the Medical Women's Federation on December 15th 1931 Dr JANET VAUGHAN read a paper on the treatment of anaemias

Knowledge of the etiology, and, therefore of the treatment of anaemias she said had advanced rapidly during the last few years since something was known to day of the factors controlling haematopoiesis Normal haematopoiesis was dependent upon adequate supplies of iron and copper of at least two substances present in whole liver of vitamin C, of some complex of vitamin B and of thyroxine A deficiency of one or more of these factors might be brought about by faulty diet digestion absorption, or distribution or by excessive strain placed on the normal storage depots by haemorrhage or pregnancy Dr Vaughan classified as iron deficiency anaemias (1) idiopathic microcytic (or hypochromic) anaemia including the Plummer Vinson syndrome, (2) anaemia following acute and chronic haemorrhage and (3) the simple or nutritional anaemia of infancy In idiopathic microcytic anaemia faulty absorption due to achlorhydria played a part in some instances since typical cases occurred with normal gastric acidity but she did not consider that lack of acid was the sole cause any more than it was in pernicious anaemia Failure of distribution through damaged blood vessels occurred in some cases since arterio sclerotic patients responded less well to iron than patients with normal vessels The history usually obtained from such patients also pointed to the importance of faulty diet The influence of iron poor diet was illustrated by the after histories of a series of patients with gastric haemorrhage A small group of such patients treated with massive iron dosage showed a more rapid gain of both haemoglobin and red cells than a control group which did not receive iron Quoting Mackay's work, Dr Vaughan emphasized the importance of iron intake in the anaemia of infancy In the treatment of the microcytic anaemias large doses of iron—60 to 120 grains of Blaud's pill or of iron ammonium citrate a day—were essential It was still difficult to assess the value of

Reviews

RADIOGRAPHY OF BONE

[illegible]

coxa vara are put near to the rachitic coxa vara and the coxa vara due to fractures Rare bone lesions which are more or less medical curiosities are omitted, as their practical importance is small compared with tuberculous lesions to which considerable space is allotted Further more radiography contributes to the differential diagnosis of tuberculosis of bone and assists the clinician in deciding on the correct treatment since it gives him a guide as to the stage of the disease The authors state that the diagnosis of a tuberculous lesion of bone is made by radiography which besides indicating the gravity of the case allows its progress to be followed All works of this kind have their limitations, and if these are recognized by the student he will not fall into the error of thinking he can obtain a knowledge of radiology by looking at reproductions (however good) of *x* ray films Such books are of use in so far as they provide excellent illustrations with diagrams wherever necessary to make plain the lesions of typical bone injuries and diseases They do not teach the student how to interpret *x* ray pictures or how to correlate pathological changes with radiographic appearances In other words this atlas does not provide an easy method of acquiring a knowledge of radiology, but is useful as a work of reference The radiographs are numerous and of a uniformly good quality Where because of the nature of the lesion there is difficulty in obtaining a clear reproduction—this in itself often being a diagnostic point—the accompanying diagram adequately serves its purpose

A SURVEY OF TUBERCULOSIS

The Results of the Investigation on Tuberculous Disease [2] by a number of German authors is a storehouse of information of an eminently practical character, which will be found as valuable and deserving of study by the general practitioner as by the scientific worker Two volumes have already been issued and were referred to in these columns on October 11th, 1930 (p 603) and on May 16th 1931 (p 850) The third volume, now published contains eight extensive articles on the pathological anatomy of pulmonary tuberculosis at puberty the clinical aspect of pulmonary tuberculosis at puberty the significance of heredity and constitution pulmonary tuberculosis and pregnancy primary abdominal tuberculosis in childhood pneumonoconiosis and tubercle general treatment and the Government control of tuberculosis

Lack of space precludes an adequate review of these articles every one of which is deserving of consideration, but the general conclusions of the first two may be briefly referred to The course taken by a primary infection of the lung naturally varies in different cases but statistics have shown that a very frequent type is that in which an infection in childhood becomes quiescent for some years and is followed by renewed activity of the disease at the time of puberty Statistics point to a marked sudden increase in the rate of incidence at puberty and in these cases which appear to be the starting point of the majority of cases of adult pulmonary tuberculosis the quiescent focus of an earlier infection dating from childhood is usually to be found Cases of this type may be said to exhibit two stages—that of the primary infection and that of exacerbation at puberty The question discussed by the authors—an important one from the point of view of prophylaxis—relates to the cause of the exacerbation at puberty The opinion commonly held that a feeble constitution and an innate disposition to tuberculosis cause a breakdown of the resisting powers at a time when the constitution is suddenly taxed with the onset of sexual development is probably misleading

[2] *Ergebnisse der Gesamten Tuberkuloseforschung* Herausgegeben von H Assmann H Brützke H Braeuning St Engel Band iii Leipzig G Thieme 1931 (Pp 695 143 figures M 64)

It has been observed that the majority of these patients are of a healthy and flourishing type and it has also been noticed that some cases apparently become worse instead of better under sanatorium treatment The theory put forward by the authors, and supported by reasoning of much cogency, is that the main cause of the exacerbation at puberty is an increased activity of the vegetative processes of the body, induced by the new hormones thrown into the system at that time—that the primary focus of childhood is reactivated by these and, in addition, is generally reinforced by a superinfection with tubercle bacilli from without Treatment directed towards increasing the resisting power by endeavouring to improve the general health is, therefore, probably of little use and modification of the secretion of hormones is beyond our power The obvious indications are to adopt all possible measures to prevent infection in childhood, and to protect the subject at the time of puberty from exposure to sources of reinfection While it would be Utopian to suppose that complete success in eliminating the exacerbation of tubercle at puberty is to be obtained by these means the authors contend that as the disease can be brought under observation in an early stage in these cases, it can be submitted to *modern methods* of treatment which, in that stage, have been attended with a considerable degree of success

THE LITERATURE ON VITAMINS

A review of the literature on vitamins [3] by Dr ETHEL BROWNING is a comprehensive monograph published by the Pickett Thomson Research Laboratory whose publications hitherto have been devoted to bacteriology The scale of the work is indicated by the fact that it contains 432 pages of letterpress and 90 pages of bibliography and the first point that impresses the reviewer is the enormous amount of labour that has been put into its preparation One of the chief obstacles to the study of vitamins is the literature of the subject This literature the total bulk of which is enormous consists chiefly of short papers scattered through a wide variety of journals Examination of the volume under notice shows that the author has ransacked this heap of printed matter very thoroughly We have not noted any omissions of importance, the literature down to the end of 1930 has been covered and there are even references to work published in the current year

The first question about such a survey is whether it covers the evidence fully but there is a second question equally important—namely, whether the evidence has been digested properly This is a very difficult task in the case of a subject like vitamin research because the evidence is most contradictory, and also of very varying merit The uncritical accumulation of references results only too often in the information that about an equal number of workers voted either for black or for white while the remainder favoured varying shades of grey Dr Browning however has worked up her material with care and judgement and indicates clearly her opinion of the relative value of the evidence presented A pleasing feature of the volume is that it goes as fully into the physiological as into the biochemical properties of vitamins So much attention has been paid of late years to the investigation of the chemical nature of vitamins that the primary problem of the actions they can produce on the living body has been somewhat neglected In particular the author discusses carefully the evidence regarding various problems of fundamental physiological importance—for example the relation between vitamins

[3] *The Vitamins* By Ethel Browning M D Monographs of the Pickett Thomson Research Laboratory Vol i London Baillière Tindall and Cox Baltimore The Williams and Wilkins Company 1931 (Pp xxx + 575 42s net)

... and ... and ... The introduction has ... of ... and ... and ... and

The September number of the *Annals of Medical History* bears on its cover a portrait of Erasmus Darwin (1731–1802) of Lichfield grandfather of Charles Darwin and Francis Galton His various activities, and especially his views on evolution and heredity are described by Dr E B Krumbhaar Theodore Kocher of Berne whose portrait forms the frontispiece, is shown by Drs E R Wiese and J B Gilbert to have had artistic abilities, and, next to Billroth to have done probably more than anyone else to make gastro intestinal surgery a science Dr C Elgood of Teheran gives a translation of the earliest Persian monograph on syphilis dating from the sixteenth century In a scholarly and well illustrated article entitled From Epidauros to Galenos Dr A P Cawadias traces the evolution of Greek medical thought and prefers on etymological grounds to use the name Galenos in preference to the usual and shorter one In describing the origin of the name Alopecia areata Dr D W Montgomery draws attention to the clinical history of this remarkable affection Dr William Browning's article on the relation of physicians to early American geology contains a list of a hundred medical men who thus justified the definition of medicine as the mother of the sciences Dr R P Parsons gives a most attractive picture of the 'adventurous Joseph Goldberger who was born in 1874 and died about three years ago he was prominent in the Public Health Service and famous for his investigations in pellagra Dr Robert Wilson of Charleston South Carolina gives an account of J C Nott of Mobile, Alabama who as long ago as 1848 came to the conclusion that yellow fever was transmitted by mosquitos and other insects In an article on Phineas Fletcher and his poem *The Purple Island* (1633) Dr Samuel W Lambert of New York shows that this non medical author's anatomy was fairly in accord with that of Vesalius but that his physiology was that of Galen

Professor GODBOLE'S monograph on butter fat[8] deals chiefly with methods of detecting impurities in ghee He points out that vast quantities of ghee are consumed in India and that it forms a most important item of the diet of large sections of the population It is freely adulterated at the present time with cheaper vegetable fats and while the author does not seem to suggest that these have deleterious effects on the consumer it is evident that the practice enables the vendor to make quite unfair profits Professor Godbole reviews the current chemical and physical methods for estimating the constituents of mixtures of fats he finds them all unsatisfactory and proposes a method of his own depending on the use of a refractometer It seems difficult to see how it is possible to distinguish between vegetable fats added to the butter in the process of manufacture of ghee and those added as it were *in vivo* by feeding the cows on oil cake etc Would the latter be classed as adulterants?

The forty eighth edition of *The Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland*[9] for the session 1930–31 is a much slimmer volume than its predecessors and can be purchased for about half the price While the abridgement and economy in price have been achieved by omitting the Lists of papers read hitherto a feature of the *Year Book* readers are reminded that secretaries of societies will always supply full particulars of papers read and of those published and available for purchase All other customary information is returned so that in its new form the *Year Book* constitutes a convenient and authoritative guide to the numerous scientific and learned societies The medical section which contains lists of publications issued by the Ministry of Health the Medical Research Council the British Medical Association and the Royal Society of Medicine, is similar in arrangement to that of its predecessors and there is a classified list of medical societies other than those respecting which information is given in the body of the book

The third edition of the Natural History Museum's pamphlet on *Rats and Mice as Enemies of Mankind*[10] has recently appeared There are a number of minor corrections and additions especially in relation to the re-establishment of the black rat in many places in the past few years, to the Rats and Mice (Destruction) Act of 1919 and to the Rodier system for rat extermination The pamphlet keeps to the same general plan followed in previous editions, and it continues to give a very useful account of the economic and medical importance of rats and mice

The Smoke Abatement Handbook[11] is a useful summary of up to date information on all aspects of this problem There are notes on smoke and health, smokeless fuels atmospheric pollution, and on Scots and English law relating to the emission of smoke Lists are also given of the principal books on the subject and of the local authorities affiliated to the Smoke Abatement Society As the handbook is designed for ready reference we suggest that future editions should be printed in larger type

PREPARATIONS AND APPLIANCES

UTERINE CANNULA FOR THE RUBIN TEST

Major W C SPACKMAN FRCS Ed IMS (civil surgeon Poona India) writes

The uterine cannula here illustrated has been made for me by Down Bros Ltd (St Thomas's Street London S E) and has proved very effective in use It is designed to be used for the rubin test for patency of the Fallopian tubes with any of the inflation methods Its special feature is the sliding bracket to take the finger holes of the vulsellum The latter is applied as usual to get a good grip of the cervix on its vaginal aspect in the anterior fornix The cannula is now passed in the usual manner (it is of such a size that no dilatation is needed as a rule) till the acorn is firmly pressed into the external os The handle of the vulsellum is now applied on to the two hooks of the bracket which is firmly braced outwards by two fingers of the right hand against the pressure of the thumb of the same hand on the thumb grip on the outer end of the cannula When by this means the tension of the acorn against the cervix is deemed to be adequate the bracket is fixed by the finger screw provided The cannula and vulsellum are thus easily controlled by one hand while the inflation is carried out

British Medical Journal

SATURDAY JANUARY 9th 1932

THE APPROVED SOCIETIES VALUATION

The report by the Government Actuary Sir Alfred Watson on the third valuation of the assets and liabilities of approved societies has now been presented to Parliament by the Minister of Health A synopsis was given in the *Supplement* to our issue of December 26th 1931 (p 338) What has become the usual sequence of events occurred Prior to the valuation somewhat alarming rumours were allowed to get into circulation Officials of approved societies permitted it to be said or understood that their funds were in a very serious state of depletion that the valuation is about to disclose results which are most disquieting and that the consequence of additional benefits or lower contributions will in most cases be impossible Next comes the valuation which is hailed apparently with relief that the results are going to prove less disastrous than had been supposed though they will be far from satisfactory Then when the valuation is complete the results are found in general to be very good and for a large proportion of the insured population not only can additional benefits be granted but contributions actually be increased even though a large percentage of the ascertained surpluses are required to be placed to the contingency fund The threatened bankruptcy of the insurance funds is once more averted A small number of the approved societies are found to be in a bad financial condition and certain complex and even vicious features are discovered whereupon the officials of important societies point to these facts as justifying the accumulation of still larger reserves and the piling up of still more balances That are not the views in the world though caution seems often to be carried to excess In these circumstances it is desirable to understand what exactly the valuation is and what are broadly its main results and to consider those features which disclose the need for some reconsideration of parts of the national health insurance system

The process of valuation is applied to insurance benefits to ascertain on the future contributions of the present members of the approved societies and the future contributions which will be required to provide the benefits of future members of the approved societies The valuation is made by comparing the present value of the future benefits with the present value of the future contributions plus the present assets of the funds The present value of future benefits is found by multiplying the amount of each benefit which will be payable in each future year by the probability that a person of the age in question will be in receipt of that benefit in that year and by the present value of a pound due in that year The present value of future contributions is found by multiplying the amount of the contribution payable in each future year by the probability that a person of the age in question will be paying contributions in that year and by the present value of a pound due in that year The present assets of the funds are taken at their book value [illegible] The valuation is made as at December 31st 1929 and the results are brought forward to December 31st 1931 by taking account of the transactions during the intervening two years Here [illegible] the present value of future benefits [illegible] the present value of future contributions [illegible] the present assets [illegible] the valuation [illegible] the valuation [illegible] the valuation

calls urgently for the reduction of the rate of their disablement benefit to one half of that of their sickness benefit as in the case of men In the third place, the position of married women within the insurance scheme, requires immediate consideration It appears that in their case no increase in contributions which would be socially tolerable could provide for the benefits to which they are at present entitled So far as the cash payments during sickness and disablement are concerned, it should be recognized that they are, in fact, an uninsurable proposition, at any rate within certain age limits in ordinary circumstances

In conclusion it is necessary to emphasize the protest of the medical profession against the false logic of the penultimate paragraph of the report Though the position is there set out with more moderation than has sometimes been the case it is certainly untrue, except to a very limited extent that " it is conclusively shown by the results of the late survey of a sample of the claims that causes of excess which are definitely controllable have been in operation " These alleged causes are stated to be laxity in medical certification and in the supervision of claims by societies There are a number of societies whose administration is unsatisfactory and there has from the beginning been a small proportion of cases in which medical certificates have been given without full regard to the requirements of the insurance scheme but there is no reason to suppose or suggest that either of these things has varied with the exigencies of the economic situation The general health of the population must be in some degree affected by this situation but it should by this time be abundantly clear that the main factor which does vary in accordance with economic stringency is the number of legitimate claims which the insured population make This and this alone is sufficient to explain the increase of claims to sickness and disablement benefit during the period of the great coal strike and during recent years of industrial depression

HENRY MAUDSLEY

" Testimonied in his own bringings-forth ' It was a singularly happy thought that led Sir Hubert Bond to choose these words as the text and subtitle of his recent Maudsley Lecture before the Royal Medico-thin its pri Association Maudsley himself had half the price ' the title of his essay on Shakespeare, price have been ach papers read hitherto a le-been an ardent and lifelong ire reminded that secretaries of -that passage in *Measure* full particulars of papers read and of the the calumnies available for purchase All other customa- is retained so that in its new form the *Yo*, who was stitutes a convenient and authoritative guy in you, '

Annals of Medical History New Series vol iii No 1 stream of 1931 New York Paul B Hoeber Inc Ltd must upon Tindall and Cox (Subscriptions in Great Britain of six numbers) roclamation Let

Butter fat (Ghee) By Professor N N gings-forth B Sc Benares Department of Industri Hindu University 1930 (Pp 43 4s) the lecturer kept

The Official Year Book of the Scientific Henry Maudsley's *of Great Britain and Ireland* Compile- the business he had Forty-eighth annual issue London C 1931 (Pp viii + 171 10s net)

helmed was often enough fraught with difficulties, but with difficulties which later were proved to be blessings in disguise, and bearing testimony to the numerous bringings-forth of Maudsley's productive genius, his philosophical and psychiatrical writings, his sociological prescience, and his liberality

The psychiatrist has perforce to be a student of human nature, and cannot afford to neglect such profound psychological studies as are delineated in the works of Shakespeare With that great mind Maudsley had an intuitive correspondence, and Sir Hubert Bond rendered a timely service to Maudsley's memory in urging upon his hearers the perusal of Maudsley's two Shakespearean essays the *Essay on Hamlet*, published in 1865 at the outset of his professional career, and his *Essay on Shakespeare* which appeared more than forty years later The lecturer referred to these essays as of arresting interest and merit, and as affording lessons of the highest value to those whose work in the treatment of mental disorder may require for its success an ability to analyse character Among the difficulties which beset the business Maudsley " helmed " not the least was the exasperating delay in the creation of the Maudsley Hospital This postponement of the fruition of his plan for the treatment of early cases of mental disorder led however, to unforeseen benefits The delays attendant on its creation had caused Maudsley no little disappointment, but Sir Hubert Bond reminded his hearers that, but for such delays the Maudsley Hospital might never have started its career as part of the 4th London General Hospital during the war and therefore might never have accomplished the fine piece of work it did for the neurasthenic and ' shell-shock " cases among the soldiers Moreover, but for the valuable therapeutic administrative and legal lessons that had been learned, the inauguration of treatment of mental illness in its early stages might have had to encounter many handicaps In paying tribute to the fertile conception of Henry Maudsley's mind, and to the excellence of the work undertaken at the Maudsley Hospital Sir Hubert Bond reminded all concerned that there is now in operation the Mental Treatment Act, and that under that Act the provision of other hospitals with functions analogous to those of the Maudsley Hospital is not only permitted but encouraged especially in conjunction with voluntary general hospitals and in particular, among the latter, with those associated with medical schools

To the majority of persons Maudsley's fame will reside in the hospital named after him in the fertility of imagination which gave birth to the project for the treatment of early cases of mental disorder, in the persistence with which he pursued it, and the self-denying ordinance whereby it became possible Others prefer to ascribe Maudsley's entitlement to fame to his contributions to scientific philosophy, and especially to his upholding of the essential unity of the human organism Maudsley's absorption in metaphysical problems is perhaps the reason for the present-day neglect of his writings other than the *Pathology of Mind* by

psychiatrical students. His philosophical approach to the subject seemed at times to obscure it, but a closer reading never fails to bring out the deeper truths to which his mind is ably tended. With the exception we have just mentioned, Maudsley's writings are too little known to the present generation, and not the least of Sir Hubert Bond's services in his appreciation of Maudsley has been to re-create an interest in his writings both as a source of knowledge and as a means of mental discipline. But neither in the hospital which stands as a memorial to Maudsley's vision and benevolence nor in his philosophical contributions does the Maudsley lecture consider Maudsley's claim on posterity to be exhausted; and not the least interesting and stimulating part of his discourse was his portrayal of Maudsley's uncanny presence of mind of our current scientific and religious views and of our economic distresses. Sir Hubert Bond instanced as a hint at modern conceptions of the universe that passage where Maudsley considers the effect of transcending the present by accumulating in thought those conditions or generalizations of human perception which are called space and time; and quoting from Maudsley's *Organ to Himself* reminded his hearers of the warning that "Decay in the body politic tends to disease and death as unremedied tends to death" nor did he feel it to be inconsistent with Maudsley's prophecies to declare that in some sections of the community it was an actual decline in religion that lay at the root of most of our present troubles, difficulties and perplexities.

NEW YEAR HONOURS

The New Year Honours announced on January 1st include the names of sixteen members of the medical profession. Dr. Walter Elliot's services to the State in various Ministerial capacities are appropriately rewarded with a Privy Councillorship. Sir Leonard Rogers, president of the India Office Medical Board, receives the further honour of K.C.S.I. Sir James Kingston Fowler, a member of the Colonial Advisory Medical Committee and for many years honorary secretary of the Beit Memorial Fellowship for Medical Research, is promoted K.C.M.G. and Dr. John Weir, K.C.V.O. Dr. [illegible], Medical Officer of Health of the London County Council, is created K.B.E., and the honour of D.B.E. is conferred on Dr. [illegible], who went to India forty years ago [illegible] for the Indian Zenana Mission [illegible] Dr. [illegible] Dr. [illegible] K.C.S.I. [illegible] Dr. D. J. Hasbi[illegible] [illegible] 1927 [illegible] 1925. Mr. [illegible] [illegible] Dr. [illegible] Dr. [illegible] [illegible] Dr. [illegible] [illegible] [illegible]

and 29 from disease The incidence rate was 4 2 per 1,000, showing a slight increase, from 3 4 in 1929 Of the total deaths from injury, flying accidents accounted for 66 per cent , compared with 56 per cent in 1929 68 per cent in 1928, 70 per cent in 1927, and 73 per cent in 1926 Invalids to the number of 121 were transferred from commands abroad to the United Kingdom the chief causes being disease of the nervous system and brain 22, digestive system 18, injuries 18, and diseases of the respiratory system 18 The incidence rate of 12 8 per 1,000, and the final invaliding rate from the Service of 5 8 per 1 000 are the lowest on record The report concludes with some informative details of the Service, among which are particulars of the Central Medical Establishment the physical efficiency of serving officers and airmen pilots of the Royal Air Force and the medical examination of recruits Other items of interest concern the transfer of casualties by air and the formation of the Royal Air Force dental branch in July, 1930 The importance of dentistry is fully appreciated to day and many will sympathize with the natural desire of the Royal Air Force to possess its own dental service The practical economist, however, in a time of financial upheaval may regard it as an unnecessary expenditure having in mind that this departure would eventually mean an increased administrative staff and that dentistry, although an important branch of medicine, plays no part in tactical operations during active service The units of the Royal Air Force are comparatively small, and are at times fairly widely scattered in the Mediterranean littoral and Iraq If their personnel are to receive proper dental attention the Royal Air Force dental officers will either have to travel considerable distances at frequent intervals thus incurring additional expense, or hand over their cases to the nearest naval or military dental officer Here was an opportunity to experiment in the formation of an imperial dental department for all the fighting Services

WELFARE OF THE BLIND

Since 1868, when Dr T R Armitage brought into being the British and Foreign Blind Association, and introduced into England the Braille system of reading and writing public interest in the welfare of the blind steadily increased until in 1902 the association was transformed from a semi-private undertaking into an incorporated society In its report for the year ending March 31st 1931 gratitude is expressed for the warm sympathy that has been extended on all sides to the Institute the requirements of which are however, still in excess of the support received The total sum bequeathed to it during the period under review amounted to over £20 000 and it is hoped that in spite of the persistent financial depression the great needs of the blind will not be forgotten An account is given of the various sides of the work carried on by the National Institute and mention is made of the success that has attended the training of blind masseurs The institute s rotary press is the latest type of Braille printing press it can print 16 000 pages an hour as compared with the 3 000 pages an hour of the Institute s other presses During the year the number of books and periodicals published was as follows bound volumes and general literature, 27 000 pamphlets 15 000 magazines, 234 000 newspapers 345 000 , and stereotyped plates for books, magazines, and newspapers, 22,000 There has been a notable increase in the number of bound volumes produced due mainly to the installation of the rotary press The subcommittee on technical research has been actively engaged in providing apparatus for educating the blind, and securing them access to museums and other educational centres

INFANTILE PARALYSIS IN THE U S A.

The 1931 epidemic of poliomyelitis according to a recent bulletin issued by the Metropolitan Life Insurance Company, New York, was the most extensive and destructive which has visited the United States since 1916 Nineteen States with an aggregate population of over 80 million persons, yielded a total of 13 091 cases (a sickness rate of 21 per 100 000 population) The highest sick rate reported in 1931 was in Connecticut, with 78 9 per 100,000, while other States with case rates above the average were New Jersey (26 2 per 100,000), New York (55 3 per 100,000), Massachusetts (37 4 per 100,000), Michigan (37 4 per 100 000), Minnesota (31 per 100 000), Rhode Island (28 9 per 100 000), Vermont (29 3 per 100,000), and Wisconsin (28 7 per 100 000) Nevertheless the case mortality from poliomyelitis in 1931 was much lower than in 1916, as is illustrated by the fact that the total of 404 deaths from this cause among children in the Metropolitan Life Assurance Company during the first forty-three weeks of 1931 was 81 per cent below the number which would have occurred if the death rate had been the same as in 1916 There also appears to have been a lower incidence of crippling

According to a cable from New York, published in the *Times* of January 2nd the results of recent work by Dr Frederick Eberson assistant professor of medicine in the University of California Medical School on the infective agent of infantile paralysis were presented by him to the American Association for the Advancement of Science on December 31st, 1931

THE TONSIL AS A FOCUS OF INFECTION

Dr G Worms and Dr J M Le Mee have written an important monograph on the tonsil as a focus of infection [1] It is based on the information derived from an elaborate questionary addressed to a large number of laryngologists throughout Europe and America The replies have been classified and moulded into an orderly report with remarkable judgement and sense of values The authors have achieved this by not allowing their own opinions and conclusions to be obscured by a mass of detail, although they render full credit and acknowledgement for the help they have received The recognition of the tonsil as an important focus of septic infection does not in itself imply what a vast field of inquiry can spring from this limited area and it needs such a work as this to indicate how wide and remote are the possible effects The authors have realized fully the possibilities latent in their undertaking and were naturally prepared for a great diversity and shading of opinion The survey includes the influence of tonsillar infections in septicaemia, the various forms of rheumatism endocarditis nephritis gastro-intestinal and hepatic disorders their effect on the thyroid gland

FACTORS IN THE PROBLEM OF TUBERCULOSIS

BY

J MIDDLETON MARTIN M D

COUNTY MEDICAL OFFICER OF HEALTH GLOUCESTERSHIRE

In the following numbered paragraphs I have set out what appear to me to be salient facts in the consideration of the problem of tuberculosis all of which must have due weight in our conclusions for administrative purposes They could be extended considerably but those given seem to cover the essential aspects

1 It is generally accepted that tuberculous infection is almost universal in this and some other countries—for example 90 per cent of children under the age of 15 in large towns in Europe and America react to tuberculin tests [1] In a study of post mortem records Vining showed that 50 per cent of 563 children between the ages of 5 and 15 had tuberculous lesions, and that in the case of 103 deaths from accidents 14 (13 5 per cent) showed such lesions

2 Between 1838–42 and 1911–15 the pulmonary tuberculosis death rate in England and Wales fell steadily from 3 78 per 1 000 to 1 05 It has been suggested that the fall has been more rapid since treatment schemes were adopted In support of this Sir Robert Philip[2] quoted Birmingham figures (tuberculosis all forms) showing a percentage decrease ' of 4 15 between 1883 87 and 1898–1902 and a similar decrease between 1903–7 and 1918–22 of 24 24 This was indicated also by the report of the Registrar General for 1920 In England and Wales for the years (as nearly as possible) taken by Sir Robert Philip for Birmingham the figures for the pulmonary tuberculosis death rate are

1881–1885	1 83	1901–1905	1 22
1896–1900	1 32	1921–1925	0 86
Fall	0 51	Fall	0 36
Decrease per cent	27 8	Decrease per cent	29 5

Had the figure for 1916–20 (1 10) been taken instead of that for 1921–25 the fall for the interval of fifteen years (taken by Sir Robert Philip) would have been only 9 9 per cent

3 The numbers of persons in Gloucestershire at any given time known to have had illness leading to notification as suffering from tuberculosis are about 2 000 for pulmonary tuberculosis and about 1 000 for non pulmonary tuberculosis—a total of 3 000 or about 1 per cent of the population This implies that some 99 per cent of the population have been infected in early years of life but at no time have presented signs of illness which were attributed to tuberculosis

4 In some countries illnesses from tuberculosis are exceedingly acute [1] For example in the case of Indians of the Canadian plains tuberculosis was almost epidemic from 1884 to 1904 and then subsided gradually Even now the death rate among Indians is about 8 per 1 000 or nearly twenty times that of the surrounding white population Ferguson (Saskatchewan) reported that 90 per cent of school children reacted positively to tuberculin In French equatorial Africa the primitive races show severe and rapidly progressive forms (Vassal)

5 The incidence of bovine tuberculosis in cattle in this country is indicated by the following figures 40 per cent of cows react to tuberculin and 7 per cent of milk is tuberculous

6 Only a small proportion of children can be or can have been in close association with known cases of human tuberculosis yet of 229 bone and joint cases among children under 10 years of age reported by A Stanley Griffiths [6] the organisms in 164 cases (71 6 per cent) were regarded as due to the human type in 59 (25 7 per cent) as due to the bovine type and in 6 (2 6 per cent) as atypical

7 On the other hand most children have the opportunity of drinking cow's milk 7 per cent of the samples of which are reported to be infected with the bovine form of the bacillus

8 As children grow older, the proportion of cases of bone and joint tuberculosis attributed to the bovine organism is reported to fall as follows [7]

Under 5 years	32 8 per cent
5 to 9 years	24 5 "
10 to 15 years	12 1 "
16 to 24 years	10 5 "
25 years and over	0 "

9 The type of organism reported in cases of pulmonary tuberculosis is almost invariably the human form but occasionally it is described as the bovine type Thus B Lange[8] reports four such cases in one the bovine were mixed with human bacilli

10 To account for the discovery of the human type of organism in pulmonary tuberculosis the explanation (originating it is believed in the United States) put forward is infection later in life by a new bacillus of the human type though it is more or less generally accepted that immunity more or less complete is afforded by early infection Massive doses are regarded as leading to the reinfection Presumably such massive infection could obtain no more effectually than between husband and wife but there is little evidence of conjugal infection [9] In his Lady Priestley Memorial Lecture to the National Health Society on November 29th 1912 Professor Elie Metchnikoff related his own experience attributing his immunity to infection from a tuberculous wife to non pulmonary trouble early in life

At the age of 23 he married a woman of the same age who was so ill with pulmonary tuberculosis that she had to be carried in a chair up the few steps leading to the church She died from tuberculosis four years afterwards He passed the greater part of that time by her side in the greatest intimacy without taking any precaution against the contagion His explanation of his immunity was that he suffered from ophthalmic scrofula when young and at the time of speaking had ganglia in the neck ' very probably of bacillar origin

11 In view of the facts (*a*) that it is rarely that pulmonary tuberculosis occurs in a person with marked evidence of non pulmonary lesion (*b*) that there is little if any evidence that even such massive infection as is possible under conjugal conditions produces pulmonary tuberculosis, and (*c*) that tuberculous infection in early life is almost universal in this country and illness due thereto is exceptional the conclusion would appear to be that pulmonary tuberculosis in later life occurs in members of the population who have not had much active tuberculous infection when young and in whom marked immunity by such tuberculous infection has not been produced

12 The explanation at the present time of the occurrence of pulmonary tuberculosis in later life is reinfection (see 10) and the necessity for such an explanation appears to be the character of the organism found—mainly the human type as contrasted with the ' bovine type

13 The distinction between these two main types is based on cultural and virulence characteristics of rather a refined nature Ordinarily an organism conforms generally to one or other of the main types but this is not always the case For example Dr Stanley Griffiths[10] observes in his note on the second series of 261 cases

No difficulty was found in classifying the cultures from 251 cases There remain 10 viruses the cultures from which did not conform exactly either to the human or bovine type Eight of the ten were designated ' dysgonic human the remaining two atypical ' viruses are more difficult to classify Finally—for reasons which he sets out—he concludes the combination of characteristics justifies in my opinion the classification of these two viruses as attenuated bovine

14 This difficulty is further evidenced in the recent investigation of the Lubeck catastrophe following the use

a whitish unbaked clay answered to the same test as the terra sigillata of Malta which was famous in the Middle Ages as an antidote to poisons and for counteracting the effects of the bites of venomous reptiles

The story of how St Paul came to be associated with this clay taken from a cave on the shores of Malta is recorded in the New Testament

About the year 60 A.D. the apostle Paul after appealing to the Emperor to be permitted to come to Rome embarked in a ship from Alexandria in the charge of Julius the centurion. Storms and rough weather were encountered and the vessel was wrecked the passengers being washed ashore on an island which proved to be Malta. They were received with kindness by the people who gave them shelter in a cave from the cold and rain.

When Paul had gathered a bundle of sticks and laid them on the fire, continues the text, there came a viper out of the heat and fastened on his hand. And he shook off the beast into the fire and felt no harm. To the amazement of the onlookers. Howbeit they looked when he should have swollen or fallen down dead suddenly but after they had looked a great while and saw no harm come to him they changed their minds and said that he was a god.[1]

According to a later tradition Paul when he landed in Malta endowed the earth of the island with the power of curing the bites of venomous beasts and rendered harmless all snakes and scorpions for ever. Some of these when taken to Sicily immediately became venomous again while on the other hand poisonous reptiles introduced into Malta suddenly became harmless.

There was a common belief among the Maltese that persons born on January 25th the anniversary of the conversion of St Paul were immune from the effects of poisonous bites and stings and that the simple act of licking or sucking the part was sufficient to cure them. It is said that in the Middle Ages charlatans who pretended that they were descendants of St Paul's followers perambulated the island claiming that their origin protected them from poisonous snakes.

The cave in which St Paul is said to have taken refuge is near the parish church at Rabat about eight miles from Valetta and a statue of the apostle which now stands within it was erected by the Grand Master Pinto. The superimposed Collegiate Church dedicated to St Publius was rebuilt in 1692.

The chalky earth or clay which is supposed to have the property of resisting poisons was formerly called St Paul's Grace and as it was gradually removed from the sides and floor of the cave to be stamped and made into tablets it was said to be miraculously replaced. Like the sacred sealed earth or terra sigillata from the island of Lemnos it acquired a reputation throughout Europe and such was the demand for it in the fifteenth century that the Grand Masters of the Knights of Malta took official charge of its collection and distribution and had it stamped or impressed with certain seals seventeen varieties of which are known. Olaus Worm gives representations of several of the stamps used in 1655. One bears the Cross of Malta on one side and on the reverse a figure of St Paul holding a staff around which a serpent is entwined. In another the apostle is represented in a kneeling position in adoration before the Pascal Lamb. Others depict him in the act of preaching while holding the staff with the serpent or show his head surrounded by a halo and a snake below. The reverse of most of the tablets bears the Maltese Cross or the arms of the Grand Masters of the Order of St John.

The earliest of the seals appears to have been the one representing St Paul holding the staff entwined with a serpent identical with that depicted on the base of the cup in the British Museum which clearly shows that it was originally made from the chalky earth or clay from the cave of St Paul at Rabat. The curious pale orange coloured stones embedded in the base were known in Malta as serpents eyes and were believed to have been fashioned by nature to perpetuate St Paul's miracle. To them also was attributed the property of averting the effects of poisons and their addition to the cup was no doubt due to the idea that they would thus render it more powerful as an antidote to any poisonous liquid that might be placed in it. They are probably the fossil teeth of a fish and vary in colour from a pale orange-brown to grey. Owing to the alexipharmic properties attributed to them they were regarded as of considerable value.

An inventory of jewels that belonged to King Henry V of England includes a number of serpents eyes garnished in gold. They were sometimes set in bracelets and in the seventeenth century there is a record that one of the Grand Masters of the Order of St John had a serpent's eye set in a ring which he wore to preserve him from colic. In 1925 Wickersheimer published the text of a pamphlet that he found in a collection formed about 1788 now in the library of the University of Strasbourg. In this the writer alludes to the precious tongues and eyes of serpents which are found in the Island of Malta and states that

> The glorious Apostle Paul when he stayed three months on the island and converted it to the faith of Christ took the poison from all the serpents that were in it rendering them harmless and inoffensive as though they were of stone at the same time giving great privileges to the rocks and soil.
>
> The virtue of the stone and of the said tongues and eyes are marvellous for they are of avail against every sort of poison and the bites of poisonous animals not only to prevent them from hurting but also to cure anyone after having taken poison or been stung or bitten by a poisonous animal.
>
> They are also helpful in many other diseases as has been experienced in the Isle of Malta and elsewhere.

The methods of using them are said to be as follows:

> The were worn in rings set with the eyes as gems so that they touch the skin.
>
> The tongues worn round the neck or arm or if infused in water for some time the liquid equired the power of rendering poisonous bites harmless.

An account of the Stone of St Paul appears in a pamphlet printed in Italian and French in Malta in 1643. It states that the Stone or Earth of St Paul also called Earth of Malta or Gratia S. Pauli is one of those clays used in medicine by reason of their absorbent astringent and sudorific qualities which are marked with a seal to testify their name of terra sigillata.

> The white earth of which we are treating here was said to come from the Grotto of St Paul over which was placed a church under the patronage of the saint. This grotto is situated at Rabatto a suburb of Civitavechia and is about eight miles from Valetta.
>
> It is very white in colour and images cups medals vases and other things are made of it.

As late as the last century the earth from St Paul's Cave was used as a febrifuge and absorbent by the Maltese, and was said to possess the same properties as magnesia. Tablets made from the dried clay were sometimes worn suspended round the neck as amulets to prevent the stings of insects. In an account of St Paul's Cave published a few years ago it is stated that in spite of the rock called St Paul's Grace having been dug away for the faithful to be kept as relics and memorials and antidotes against fevers and bites of poisonous animals it is found to have perpetually the same dimensions. From recent inquiries made by Sir Themistocles Zammit of the museum at Malta the clay from St Paul's Cave at Rabat is no longer used locally for its medicinal or supposed miraculous properties from which it would appear that the belief in its value as an antidote and alexipharmic has now died out.

THE NEW YEAR HONOURS

The List of New Year Honours was issued on January 1st as a supplement to the *London Gazette* of December 29th. It included the names of the following members of the medical profession on all of whom we offer our congratulations.

For Civil Service

Walter Ernest Fasnacht Fox MC DSc LLD MB ChB MP Emeritus Professor of Tropical Medicine, Liverpool. 1931

KCSI

Major General Sir Leonard Rogers CIE MD FRCP FRCS FRS IMS (retired) Indian Medical Service.

KCIE

Sir Lewis Knightley Dolland CVO CIE MD FRCP Member of Council, Medical Commission

KCVO

John Weir CVO MB ChB Physician to the Household in Scotland

KBE

Alexander Morse Davies MB ChB Director of Medical Services, Northern Ireland

Hermann Norton Kay Moynihan MD FRCPE FRSEd DPH Consulting Surgeon, London Clinic

DBE

Miss Ethel Mary Bedford Lloyd Lloyd MD ChB Inspector, Women's Branch, Ministry of Health

CBE

George Buchanan Bantock MB ChB FRCS Late Lecturer in the Principles and Practice of Surgery, Birmingham University

Percy Lewis Evans MB ChB FRCS Late Surgeon, Royal Infirmary, Manchester

Henry Edward Kaye MB ChB FRCP Deputy Chief Medical Officer, Ministry of Health

Harold Scott MC MB ChB 1915 Late Senior Medical Officer, Ministry of Health

CSI

Colonel John Dunlop Graham CIE IMS Indian Medical Service

CIE

Lieutenant Colonel Walter Lindsay Webb IMS Director, Bacteriological Laboratory, Kasauli

CVO

Major Thomas Alexander Lauchlan Lees TD MRCS Late Physician to the Household in Scotland

CBE

Stanley Dickinson Kelly MRCS DTM DPH Superintendent Medical Officer, Wandsworth

Percy Evans Evans-Jones MD MAMS Late Officer of Health, Gwent

Air Force Medal

Wing Commander Noel Dudley Pemberton MB ChB Principal Medical Officer, Air Defence of Great Britain Command

Flight Lieutenant Frederick Arthur Dawson MB ChB Medical Officer, Royal Air Force, Mount Batten

Queen's Police Medal

Superintendent Frederick Charles Wensley Metropolitan Police

Colonial Police Medal

Lieutenant Colonel Alexander Lamb MB ChB Commissioner of Police, Kenya

Order of the British Empire

Civil Division

CBE

Major Thomas Johnston Horsley MC MB ChB Late Consulting Physician, Ministry of Health

OBE

Edward Wyndham Kaye MRCS DTM DPH Late Superintendent Medical Officer, Wandsworth

Frederick Evans Evans-Jones MD MAMS Late Officer of Health, Gwent

Military Division

CBE

Colonel Andrew Leitch FDS Late Consulting Dental Surgeon, Ministry of Health

OBE

Major Douglas Lamb MB ChB Late Medical Officer, Ministry of Health

ANTI-MALARIA MEASURES

SIR,—In view of the [illegible] I hope you will allow me to call attention to the fact that the Malaria Committee of the Royal Society of Tropical Medicine and Hygiene has been in existence for over twenty years, and has published a number of reports on the subject of malaria and its prevention. The Committee has always been ready to give advice to any who have applied to it, and has frequently done so. The Committee has also published a number of papers on the subject of malaria and its prevention in the Transactions of the Society. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene.

The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene.

For the Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene.

The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene. The Committee has also published a number of papers on the subject of malaria and its prevention in the Journal of the Royal Society of Tropical Medicine and Hygiene.

Yours faithfully,

Colonel C [illegible]

Secretary, Malaria Committee, Royal Society of Tropical Medicine and Hygiene

[illegible]

P [illegible] I [illegible]

[illegible]

Co [illegible]

the anti larval work had not been efficiently carried out (facts which had already been reported to the directors by Mr Cantlay who was in charge of all the estates at the time of my visit) and that on some an insufficient area was being controlled—for example on one side of a group of buildings oiling was done for half a mile (40 chains) and on the other for 5 chains or even less I have my notes written at the time before me as I write now, they describe what I found and what my recommendations were

In order to put the anti larval work on a more satisfactory basis it was necessary to decide at once what area should be controlled At sea level in Malaya where malaria persists throughout the whole year, I had found that half a mile was adequate The same area has been found sufficient in certain parts of India at or near to sea level In the Travancore area malaria disappears at an elevation of about 3 500 ft The tea gardens referred to in this report ranged from 2 500 ft to 4 000 ft They were therefore near to the uppermost limit of malaria The problem which confronted me was to decide what was the probable area which would eliminate malaria completely and keep it permanently eliminated by anti larval measures alone I decided that a circle with a radius of 20 chains or a quarter of a mile should be tried If it were found insufficient it could be increased My recommendation was adopted and I have here beside me plans of all the estates showing the areas controlled by anti larval measures When I saw Colonel Clemesha in Ceylon about a month later I told him that I had found the anti larval control unsatisfactory in places and also that I had standardized the area of anti larval work to 20 chains Colonel Clemesha's report contains nothing of this so he has evidently forgotten it Yet it is of vital importance if we are to understand the reason for the improvement of health which took place in 1929

The adoption of plasmoquine after treatment was therefore not the only difference between 1928 and 1929 and in view of the facts that I have stated it cannot be regarded as the factor responsible or even mainly responsible for the improvement of health The improvement in health is what might be expected from, and did in fact follow the better organization of the anti-larval work introduced by Mr Cantlay partly on his own initiative and partly on my advice on all the estates in May 1929 and since continued by Mr Sylvester The greatest credit is due to Mr Sylvester and to Mr and Mrs Cantlay for the work they have done In giving credit to them I am in agreement with Colonel Clemesha I find myself in agreement with Colonel Clemesha on one other point It is the value of euquinine and sweetened condensed milk treatment for children He calls it a new weapon I used it more than twenty years ago as Colonel Clemesha will find by referring to the first edition of my *Prevention of Malaria in the Federated Malay States* published in 1911

Finally I would like to make it quite clear that this letter is not an attack on plasmoquine or any other anti malarial drug They have a more or less important place in *all campaigns against malaria* and I have employed them and all other methods extensively in the past and sought to determine their values and limitations as my books and papers show In some regions drugs should be used to supplement the anti larval measures until the anti larval measures by themselves are thoroughly organized and are able to prevent the further spread of the disease In other regions drugs will not be supplemental to anti larval measures they will be the method of choice and anti larval measures will not be used The dividing line between the two regions has still to be determined and I hope it will be my privilege to take part in this research Here I wish to take the opportunity of acknowledging the courtesy of Dr Schulemann director of Messrs Bayer's research department the inventors of plasmoquine when I visited him at Elberfeld in Germany and with whom I am in close communication in the researches now being carried out at the Ross Institute But what I wish to bring out now is that Colonel Clemesha's report is misleading both in what it states and in what it omits and so it does not help us to get nearer to the truth about the value or limitations of either plasmoquine or anti larval measures —I am etc,

Ross Institute Putney S W Jan 2nd — MALCOLM WATSON, Director of Tropical Hygiene

THE SOURCE OF INFECTION IN AN OUTBREAK OF PUERPERAL FEVER

SIR —Dr Leonard Colebrook does well to call attention to the fact, sometimes overlooked, that external infection may take place during the puerperium Dr Charpentier[1] gives an example fort remarquable occurring in the wife of one of his colleagues where everything had gone well up to the seventeenth day

On that day the husband on his return from treating a patient affected with a diffuse phlegmon of the thigh had the fatal idea to examine his wife to see if the uterus had returned to its normal state Next day the woman had a violent rigor and we saw unroll before our eyes the phenomena characteristic of purulent infection to which the patient succumbed on the thirty third day of her lying in

—I am etc

London W Jan 2nd — HERBERT R SPENCER

THE GRAFENBERG RING

SIR —Colonel Green Armytage's memorandum in your last issue prompts me to record the following case

Some months ago I was asked to see in consultation a lady aged 40 who complained of a slightly offensive blood stained vaginal discharge of a few months duration A Grafenberg ring had been inserted into the uterus twelve months previously, and for six months nothing untoward had happened Curettage was performed but exploration of the uterus failed to detect the presence of any foreign body The patient was told that the ring could not be found and that it had escaped from the uterus at some time or other—probably during a menstrual period The blood stained discharge persisted however and after some weeks the patient again consulted a doctor who asked me to see her

I decided to explore the uterus as I felt certain the ring must still be present An x-ray photograph would have confirmed my opinion but I did not think it was really necessary I dilated the cervix but on exploring the cavity of the uterus in the usual way with long uterine forceps and curette I could not find any trace of the ring It was only on very firm pressure with the curette that I felt it embedded in the uterine wall Removal was effected by gouging it out of the uterine wall with the curette and I was able to demonstrate the ring to the doctor with pieces of uterine muscle adherent to it The patient left the nursing home in a week's time completely cured

Discussion of this case with my colleagues brought to light the occurrence of other accidents such as acute pelvic peritonitis following the use of the Grafenberg ring and my own experience has convinced me that this is a dangerous contraceptive —I am etc

another group sensitive to a different type of antigen In ten normal cases no reaction was obtained Work is proceeding along these lines and it should be possible to answer these difficult questions in the near future — I am etc

London W 1 Jan 4th G H Oriel M D

ASTHMA STATISTICS

Sir —Dr Alexander Francis writes in your issue of December 26th 1931 that the value of the skin tests is limited to their power of disclosing certain irritants which are capable of disturbing the stability of the vasomotor system and upon which depends the asthmatic condition I entirely agree with this but why then does he do his best to belittle the value of such skin tests? A very short time has passed since both asthma and hay fever were considered to be nervous manifestations Then the fundamental fact was realized that the hay fever patient always gives a skin reaction to pollen and the horse asthmatic to horsehair From these premisses the long list of proteins for testing purposes has been prepared

For many reasons the skin tests often fail or appear to fail A certain London asthma specialist saw a child and sent home with the child's nurse a box of proteins with directions for their use ! As the child was found by her nurse to be sensitive to all the known foods further advice was sought When properly tested the child gave no reactions to any foods but a large one to cat hair not included as a test in the previous list The removal of the cat cured the child but it may not always do so This does not mean that the positive reaction to cat hair is fallacious but that the child is probably sensitive to something else perhaps house dust and so the search continues

I do not see why we should expect people to be able to correlate the results of the cutaneous tests with their experiences and beliefs as to the cause of their attacks They often do so it is true but they come to be tested to find out if possible what is the cause of their asthma, which in fact they do not know Some people are too uneducated to correlate anything A man was sent to me by his board of guardians He was found to be sensitive to feathers and the removal of the feather bed gave him three years freedom Then the asthma returned and he was sent to me again This stupid fellow was again sleeping on a feather bed

Lastly it is important to be certain that the proteins used for the skin tests are reliable A few years ago there was a set on the market which gave a reaction to fish on most arms Scores of patients were uselessly forbidden all fish on that account with of course no benefit to their symptoms Other sets are so very carefully prepared and sterilized that no protein remains in them and they are thus entirely inert as antigens Used properly the skin tests are at times very valuable and although they afford assistance in only a very small part of the problem of asthma they are a fundamental and reliable factor — I am etc

London W Dec 28th 1931 Frank Coke

GLAUCOMA

Sir —Colonel Elliot's article in the *Journal* of December 26th 1931 raises issues with which many of us would not agree It is professedly a compromise between those who treat glaucoma entirely by myotics and massage and those who treat it by operation He advocates a compromise and a compromise of this sort to me implies the best of both worlds Myotics [illegible] measures [illegible] to have the first place and operation the last How often have we seen the patient and his general practitioner go on with myotics and massage much too long before operation, thus not giving operation a fair chance! *This is the danger* Besides an iridectomy properly done in the early stage is eminently satisfactory why delay it? It is one of the simplest of operations in skilled hands, and practically devoid of risk

Many of us would not agree with his physiology He says This timing is important for, (*a*) rises in pressure occur frequently during sleeping hours owing to the withdrawal of the pumping action on the canal of Schlemm exerted by the ciliary and iris muscles What is the evidence for this statement? There is no evidence that the mechanism which circulates the aqueous is withdrawn from operation during sleep in other words that it is not automatic in the same way as respiration and the circulation of the blood is automatic The 'pumping action again we question No pumping mechanism has yet been discovered in connexion with the aqueous a sluice mechanism there is —I am etc

Henry Smith C I E
Sidcup December 27th 1931 Lieut Colonel I M S (ret)

CHLOROFORM IN LABOUR

Sir —One may suppose that ether at the Rotunda Hospital is administered without naked lights Under the usual conditions of a general practitioner's midwifery the presence of an adequate supply of ether, in close association with an *open fire paraffin lamp* or candle is to ask for a verdict of manslaughter —I am, etc ,

W J Burns Selkirk
Erdington Birmingham Dec 29th 1931

Sir —I have been in general practice for forty five years and have attended well over four thousand cases of midwifery—generally single handed I have used chloroform always and have only lost one patient over forty years ago, under chloroform The patient had been in labour two days before I was sent for had taken no food and had been given spirits She died suddenly before she was under sufficiently for me to touch her It was one of the few times that I had a skilled assistant to give it Ether is impossible, as it wants a second person to administer it

I am *strongly of opinion* that any danger there may be in administering chloroform is to be measured by the length of time the patient has been allowed to linger on in labour In private practice this very rarely occurs as the public will not have it Two *or three days in labour* is most unusual One does not hear how long cases are allowed to be in labour in public institutions —I am etc

Wallington Jan 1st A Z C Cressy

A SUBSTITUTE FOR CALAMINE LOTION

Sir —In view of the present call for economy in prescribing—a call which is not only constantly reiterated in the out-patient departments of our voluntary hospitals but which is repeated *sotto voce* in our consulting rooms by patients who have but little money to meet large chemists bills—may I remind your readers of a substitute for calamine lotion which although it is much used on the Continent and in America is not yet widely known in the British Isles? I refer to liquor aluminii acetici which when diluted to form a 1 per cent solution is as effective a substitute for calamine lotion as one could desire and may in certain cases produce a better and quicker therapeutic result

Liquor aluminii acetici is said to be non toxic and non-irritant, it certainly is very astringent The following formula gives approximately a 1 per cent solution the indications for which are precisely the same as those for calamine lotion liq aluminii acetici ʒj aq ad ʒj M fiat

in such a sort to procure abortion or non conception after the foetus shall have been already endowed with life is by law a homicide)

Section 11 —Et similiter qui dederit vel acceperit venenum sub hac intentione ne fiat generatio vel conceptio (And in like manner whoever shall have given or taken drugs to the intent that no generation or conception may take place)

Section 12 —Item facit homicidum mulier quae puerum animatum per potationem et hujus modi in ventre dejecerit (Also the woman commits homicide who by potions and drugs of that sort shall have destroyed her animate child in her womb)

Thus it will be seen that the Common Law of 600 years ago was very similar to the Statute Law of to day Mr Justice Darling in the case of Reg *v* Brown 1889 made this statement

If a woman takes a substance which is in fact harmless believing it to be a noxious thing with intent to procure her miscarriage she is guilty of the *Common Law misdemeanour* of an attempt to procure abortion (The italics are mine)

Dr Jones states that it is a Common Law maxim that there is no crime if the other party consents This is so But here although one party (the abortionist and his victim) consent the State (the other party) does not consent and so the maxim does not apply Anyone sufficiently interested in the subject will find the matter more fully dealt with in a book by me on criminal abortion which is to be published this month —I am etc

MEMBERS OF THE ROYAL COLLEGE OF SURGEONS

SIR — Brevity is the soul of wit —but not always The three lines that announce the decision of the Council of the Royal College of Surgeons of England not to grant the extremely moderate request of the Members of the College for a representation of two Members on its council out of a proposed 26 are neither witty nor wise Two things were uppermost in my mind when I came away from the annual meeting (1) When addressing the Members in his final speech the President stated, The strongest argument you have is the moral one This was a fine admission a great admission and one cannot but respect and admire the President who in the face of the memorable 24 made this fearless declaration It is this ethical principle at the back of everything that has kept this very question persistently vital for over forty years and will continue to do so till justice is established (2) The President also stated We have statutory duties to fulfil May I ask Sir what is the exact value of a statute? Surely it is an Act of Parliament instituted for the well being of any institution that has been granted a Charter for the benefit of that institution until another and a better one takes its place

Consider for a moment what would be happening at the present time had not certain statutes been rescinded or been ignored by custom Many of us would be still paying a fourpenny fine for not attending church on Sundays Again a man bearing a red flag would still be walking in front of our steam rollers and even nowadays of our motor cars! Progress means the alteration of statutes for better ones as necessary reforms are created The Royal College of Surgeons has had to alter its Charter on more than one occasion and once be it remembered it was altered for the sake of making H R H the Prince of Wales (later King Edward VII) an honorary Fellow of the College If such can take place for a single personage of royal blood it does not require a great stretch of the imagination to conceive that the same process might be repeated for the benefit of 18 000 men even if not a single one of them could boast of anything more than a plebeian ancestry —I am etc

London W 8 December 21st 1931 T WILSON PARRY

Obituary

SIR WILLIAM BENNETT K C V O F R C S

Consulting Surgeon St George's Hospital

The sudden death of Sir William Bennett at his house 3 Hyde Park Place on Christmas Eve removes one of the rapidly diminishing group of surgeons very prominent in London practice about the beginning and early years of the century and a personality with rather unusual characteristics and interests

William Henry Bennett was like some other St George's men of distinction—Sir Benjamin Brodie Thomas Tatum the surgeon and Fielding Blandford the alienist—a Wiltshire man and was born in 1852 as the son of William Francis Bennett of Chilmark near Salisbury After working for a year with an able general practitioner in the country he entered the Medical School of St George's Hospital on September 16th 1869, the school buildings of which had in the previous year been removed from Kinnerton Street to their present site His career as a student was marked by gaining the Henry Charles Johnson prize for anatomy in 1871 which carried with it the paid post of demonstrator of anatomy in the winner's third year the Treasurer's prize and the third year proficiency prize in 1872 the Treasurer's prize again in 1873 and the William Brown £100 exhibition in 1875 In 1871 he was one of a number of St George's men who started the short-lived *London Students Journal* edited by another St George's man Qualifying as M R C S and L R C P in 1873 he obtained the F R C S in 1877 in which year he succeeded J H Morgan as surgical registrar to the hospital and had a consulting room at 5 Savile Row then a select professional address Isambard Owen his colleague as medical registrar was knighted in 1902 the year after Bennett became Sir William

On the resignation of the late E C Stirling then assistant surgeon who went to South Australia and subsequently became a Fellow of the Royal Society and a knight Bennett was elected in his place in July 1880 thus defeating his senior J H Morgan (1847–1924) who in that year was elected assistant surgeon to Charing Cross Hospital After the retirement of Sir Prescott Hewett from London in 1883 Bennett who had the greatest admiration for his former chief and learnt from him two points of the greatest practical importance—namely how to talk to a private patient and the value of gentle manipulation—took his house 1 Chesterfield Street where he remained for about thirty five years of his active surgical life He worked in the out patient department for seven years, and then on December 25th 1887 after the resignation of Timothy Holmes he became full surgeon to the hospital he was thus more fortunate than his immediate junior colleague Clinton Dent who elected assistant surgeon five weeks after him served for fifteen years in the out patient department Bennett resigned from the hospital in 1905 two years before the twenty years tenure as full surgeon would have been completed and was duly elected consulting surgeon For many years until 1917 he was a member of the weekly board and of its continuation the house committee and with Sir Isambard Owen vigorously advocated the renovation of the hospital In the Medical School he lectured on surgery from 1887 to 1899 As a member of the Court of Examiners of the Royal College of Surgeons of England he examined in anatomy for the Conjoint Board and the first fellowship examinations for many years he was inspector of anatomy for the metropolis his senior colleague the late T Pickering Pick for some years holding the similar office for England and Wales For a time he examined in surgery at Cambridge

A course of three lectures with lantern illustrations on the reactions between drugs and cells will be given at University College on February 26th and 29th and March 1st at 5 15 p m by Dr A J Clark F R S professor of materia medica University of Edinburgh

UNIVERSITY OF ST ANDREWS

During the commemorative ceremonies at University College Dundee next month the honorary degree of LL D is to be conferred on Dr R C Buist honorary consulting gynaecologist Dundee Royal Infirmary and on Mr David M Greig F R C S Ed Conservator of the Museum of the Royal College of Surgeons of Edinburgh

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting held on January 1st the following were elected Honorary Fellows of the College Sir Almroth Edward Wright K B E C B M D Sc D LL D, F R C S I and Edward Francis Stephenson F R C S I D P H

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated

SURGERY —G A Dickson W Hertzog W B Mattar C Morgan P Rivlin

MEDICINE —F Crowther H T Giblin R F Hawke W W Parry S Ramarao B Shapiro E Teplitzky E O Watson H A F Wells

FORENSIC MEDICINE —J H Beale F Crowther H T Giblin J Irger V R O Lahiruni R Perkins H A T Wells

MIDWIFERY —G A Dickson R N Gillespie R F Hawke A A Kahn E J Littledale A J McBrearty J I Moohalaparacl el

The diploma of the Society entitling them (upon registration under the Medical Acts) to practise medicine surgery and midwifery has been granted to Messrs H T Giblin S Ramarao R N Gillespie E O Watson C Morgan and H A T Wells

The Services

HONORARY SURGEON TO THE KING

The Air Ministry announces that the King has approved the appointment of Air Vice Marshal John McIntyre *M C* M B B Ch, as an Honorary Surgeon to His Majesty (vice Group Captain Henry Cooper D S O who vacates the appointment on retirement from the Royal Air Force)

PROMOTION EXAMINATION

The following officers of the R A M C were approved at the examination (in written subjects) held at home stations in October last with a view to promotion Majors R E Barnsley M C W Bird J F Bourke M C T L Henderson R H C Pryn J A C Kidd F G L Dawson W O Holst Captain F C Hilton Sergeant Lieutenant J M Officer

DEATHS IN THE SERVICES

Lieut Colonel Daniel Maurice Corbett O B E R A M C died in the Royal Herbert Hospital Woolwich on December 14th 1931 aged 49 He was born on August 17th 1882 and was educated at Dublin University where he graduated as B A M B B Ch and B A O in 1905 Entering the R A M C as lieutenant on July 30th 1906 he attained the rank of lieutenant colonel on September 17th 1930 He served throughout the war of 1914-18 when he was mentioned in dispatches in the *London Gazette* of July 21st 1917 and was given a brevet majority on June 3rd 1917 and also the O B E He was stationed at Woolwich having recently returned from a tour of foreign service at Bermuda

The death in India of Lieut Colonel Zainoor Allee Ahmed Bengal Medical Service (ret) is reported without date in the Indian Army List of October 1931 He was born on July 19th 1848 and was educated in the Universities of Calcutta and Glasgow taking the L M S Calcutta in 1871 the M B Glas in 1872 and the M D in 1873 also the L F P S G and the L R C P Lond in 1872 Entering the I M S as assistant surgeon on October 1st 1872 he became surgeon on July 1st 1873 when the rank of assistant surgeon was abolished surgeon lieutenant colonel after twenty years service was placed on the selected list for promotion on April 3rd 1899 and retired with an extra compensation pension on July 19th 1903 He served on the North West Frontier of India in the Hazara campaign of 1891 (medal with clasp) on the Malakand in 1897-98 including operations in Bajaur and in the Mohmand country, was mentioned in dispatches in G G O No 178 of 1898 (medal with clasp) and in the Tirah campaign of 1897-98 with the operations in the Bara Valley (clasp) He also rejoined for service in India during the war of 1914-18

Lieut Colonel Alexander Simpson Rose R A M C (ret) died after a long illness in a London nursing home on December 12th 1931 aged 75 He was born on October 3rd 1856 and was educated at Edinburgh where he graduated as M B and C M in 1880 and as M D in 1883 Entering the Army as surgeon on February 5th 1881 he became lieutenant colonel after twenty years service and retired on May 26th 1909 He served in the Egyptian war of 1882 receiving the medal and the Khedive's bronze star and in the Sudan campaign of 1884 and in that of 1885 at Suakin receiving for each a clasp to the Egyptian medal He also served throughout the South African war of 1899-1902 going through the operations for the relief of Ladysmith including the actions of Colenso Spion Kop and Vaal Krantz where he was severely wounded and the final relief of the besieged force He was mentioned in dispatches in the *London Gazette* of February 8th 1901 and received the Queen's and King's medals with two clasps to each

Medical News

The Fellowship of Medicine and Post Graduate Medical Association announces that on Mondays and Fridays from January 11th to 29th Dr W Langdon Brown will deliver a series of six lectures on endocrinology at the Medical Society of London 11 Chandos Street Cavendish Square at 8 30 p m the fee for the course is £3 3s or 12s 6d a lecture payable at the lecture room The first of a series of nine lectures on treatment to be given on Wednesdays at 4 p m, at 11 Chandos Street will be delivered on January 13th by Dr E H R Harries these are free to members of the Fellowship, to non members the fee is £1 1s for the series or 5s a lecture Free demonstrations in medicine and surgery at various hospitals will begin on January 18th An evening course for the M R C P is being arranged to begin on February 22nd it will consist of six clinical and two pathological evenings four lectures one ophthalmic demonstration and one laboratory demonstration and will take place on Mondays Wednesdays and Fridays for four weeks The number of graduates is limited to twenty-five and they *must be members of the Fellowship fee for the course* £12 12s An evening course for the Final F R C S will take place on Tuesdays from April 5th to May 10th and on Thursdays from April 7th to May 12th open only to members of the Fellowship there are a few vacancies left Applications for all the above courses should be made to the Fellowship of Medicine 1 Wimpole Street W 1

The ninth Congress of the International Society of Surgery will be held at Madrid from March 15th to 18th At the same time there will be an exhibition of surgical instruments orthopaedic apparatus and pharmaceutical preparations, under the organization of Dr F Coca, Lagasca 38 Madrid

At the meeting of the British Institute of Radiology to be held at 32 Welbeck Street on January 14th at 8 30 p m the adjourned discussion on Dr Ffrangcon Roberts's paper "Some criticisms of the international protection recommendations will be continued by Drs Stanley Melville J Duncan White G W C Kaye and others

A course of lectures on maternity and child welfare for health visitors nurses midwives superintendents of infant welfare centres etc will be given in the Lecture Hall Carnegie House 117 Piccadilly on Mondays at 6 30 p m from January 11th to March 14th Particulars may be obtained from the secretary National Association for the Prevention of Infant Mortality 117 Piccadilly, W 1

Proportion of Rent etc for Professional Use

B N used to be allowed two thirds and later one half of the rent and similar expenses incurred by him as applicable to his professional use of his premises Recently the inspector of taxes has contended that one third would be sufficient

*** This is one of those questions where so much turns on the precise circumstances of each case that advice is difficult and may be misleading On the face of it one third hardly seems adequate especially if the waiting and consulting rooms are not used privately and if the total rent covers the use of a garage for the professional car Two points which may be mentioned are (1) that the ground floor has a much larger rental value than any other and (2) that a fair test of the proposed professional proportion can sometimes be obtained by comparing the amount of the balance left for private use with the actual accommodation available and the probable cost of that accommodation in the immediate neighbourhood

Assistant Tax not Applied for

A P M X has been in receipt of emoluments sufficient to create liability to tax since 1928–29 inclusive but has not received any income tax demand How does he stand legally and what should he do?

*** The emoluments are assessable (Schedule E) and there is no legal liability to make a return under that schedule until called upon to do so by a notice served on the recipient of the emoluments When the liability comes to light however as presumably it will sooner or later—for example through the accounts or statutory returns of the employer— A P M X will be assessable for the then current and the six preceding years On the whole it would seem desirable on general grounds for A P M X to inform the local inspector or collector of taxes that he is receiving a taxable salary if neither of them then raises the question of earlier years having regard to the voluntary disclosure so much the better for our correspondent

Appointment under the Crown Free Quarters

J S R holds a departmental appointment which carries with it the right to occupy certain free quarters Is he liable to account for income tax on the annual value of such quarters?

*** Yes—under Schedule A No VII If the employer were a private person he would be liable to account for tax on the value of the whole premises As it is the Crown is exempt but J S R has to pay on the portion occupied by him

Employment in India Emoluments

H B W is employed in India as a resident hospital physician receiving *inter alia* (*a*) free quarters (*b*) mess allowance and (*c*) servant's allowance Are these items liable to be included in computing the amount of Indian income tax payable?

*** The answer is Yes

LETTERS, NOTES, ETC

Treatment of Dysmenorrhoea

Correction

Dr ALICE E SANDERSON CLOW (Cheltenham) writes I notice with regret a misprint in my article on the treatment of dysmenorrhoea published in the last issue of the *Journal* which unfortunately confuses the import of most of a paragraph Under the heading Drugs the statement is printed is It cannot be too often repeated that alcohol and morphine should be absolutely condemned for use in a symptom occurring early in life and liable to recur monthly for many years especially as their action is generally *ineffectual* etc Whereas it is because they are *effectual* that their use is so undesirable in this particular condition

CO_2 in Resuscitation

Mr ERNEST MASSINGTON FRCS (London N 10) writes In the early hours of December 29th I had to deal with a troublesome case of asphyxia neonatorum following breech delivery Not having a cylinder of CO_2 with me I emptied half a siphon of soda water into a basin and held the baby over it Breathing commenced at once and continued with perfect regularity This treatment is so simple and efficacious that I think it is worth recording

Local Novocain and Splanchnic Anaesthesia

In the report of a clinical meeting of the Calcutta Branch published in the *Supplement* of June 6th 1931 (p 220) brief reference was made to the performance of partial gastrectomy by Major S N Mukherjee under local novocain and splanchnic anaesthesia and it was added the patient was the first in India to have this type of anaesthesia The honorary secretary of the Branch now writes Referring to the minutes of this clinical meeting I find that the statement I made was This is the first time this operation has been performed in this country under splanchnic anaesthesia I must confess that this remark was my own and not Major Mukherjee's and my justification is that I do not find any record of a Polya's operation performed anywhere in India before September 1930 but my intention was to emphasize the operation and not the novocain splanchnic anaesthesia

Delivery of a Contraceptive

Dr N HIRSCHMAN (Johannesburg South Africa) writes Some time ago I sent a *2 para* patient to the maternity home because she rang up to say that she was having labour pains and was due just about that date I received an urgent message from the sister in charge who had permission to examine the case saying that she could not locate the cervix and that she felt a something which to her did not seem in order On examination I located the cervix but protruding from it for about one eighth of an inch was the hard end of a circular tube At first I thought it was a bougie, however I removed it with an artery forceps The foreign body was the terminal portion of a whirling spray which was about three quarter of an inch long and could be screwed on for more than a quarter of an inch to the attachment of the instrument The patient continued her labour and delivered herself of a 6¾ lb infant The history shows that up to four years ago this patient had used this form of contraceptive After that for no reason she can give she used the ordinary douche can with tubing She was not aware that she had mislaid the terminal portion of the whirling spray Her periods went on normally she had no pain no excessive vaginal discharge nor could I feel any ulceration or erosion of the cervix Furthermore considering that this was a foreign body which had been lying in the cervical canal (I must presume) for about four years it is remarkable that she not only became pregnant but had no symptoms of a miscarriage or of a premature labour

Frost Precautions for Motorists

The Automobile Association sends the following suggestions for preventing damage during periods of frost (1) When a car is out of use drain radiator cylinder jackets and pump casing It is not enough on many cars to drain radiators only (2) In the absence of sufficient heating of the garage an electric or other heating apparatus of sufficient power should be employed Where these are placed under the bonnet the latter and radiator should be covered with a rug A muff is also helpful and prevents thermal waste (3) With a car in daily use introduce into the water circulating system one of the various compounds available for lowering the freezing point The A A has recently carried out refrigerator experiments to determine the best proportions of such compounds to ensure safety and information on this subject can be obtained from any of its offices

Surgical Diathermy Apparatus

Messrs Watson and Sons of Sumic House Parker Street Kingsway have sent us a booklet describing among other things the sumic chirotherm an instrument incorporating all the necessary features of a surgical diathermy equipment Considerable variations in the type and intensity of current are obtainable with this machine

Vacancies

Notifications of offices vacant in universities medical colleges and of vacant resident and other appointments at hospitals will be found at pages 43 44 45 46 47 50 and 51 of our advertisement columns and advertisements as to partnerships assistantships and locumtenencies at pages 48 and 49

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *11*

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

29 Aneurysm of the Wall of the Heart

A C Arrez (*Arch des Mal de Cœur* August 1931 p 465) has made a clinical study of the development of an aneurysm of the wall of the left ventricle The patient a syphilitic man aged 53 had for a year noticed occasional pain in the chest which spread down the left arm on effort No physical signs of heart disease were present and the orthodiagram and blood pressure were normal He then had a severe cardiac infarction accompanied by the usual fever and leucocytosis and by a reduction of the pulse rate to 30 Within a week pericardial friction appeared and a fortnight later localized bulging of the border of the left ventricle was observed on screen examination A period of gradual improvement followed during the next month but at the end of this time congestive failure set in while an x-ray investigation showed progressive enlargement upward and to the left of the left ventricle Sudden death probably by rupture terminated the illness The author remarks that although in this case radiography clinched the diagnosis in some cases an aneurysm of the heart is observed by the shadow of the diaphragm Reference is made to the stages of evolution described by Sternberg a period of anginal attacks followed by signs of pericardial irritation a short period of apparent cure and finally serious cardiac insufficiency In the case described the phase of pericarditis belonged rather to the first stage while the third and fourth stages were well marked The author remarks that patients suffering from cardiac infarction without aneurysm of the heart may show exactly the same sequence of clinical manifestations The swift evolution of aneurysm of the heart as in the author's case is specially apt to be followed by perforation while those aneurysms which develop very slowly are supported by pericardial adhesions and sclerosis of the [illegible]

30 An Epidemic of Chicken pox in Spitzbergen

J Fraus (*Tidsskr f d Norske Lægefor* October 1st 1931 p 737) gives an account of an epidemic of chicken pox which throws some light on the problems of its source and incubation period In a colony of about 500 persons including about 40 children in the coal mining settlement at Advent Bay in Spitzbergen which is completely cut off from the rest of the world for seven to eight months in the year on account of darkness and ice an epidemic of chicken pox broke out at the end of December 1930 in a family with four children The date on which the last boat had left for Norway was October 21st Three of the four children showed the characteristic chicken pox rash in various stages of development when examined on December 31st The mother had noticed a rash on December 27th but had taken the children to a Christmas party on this date Spread of the infection was therefore to be suspected although the parents were certain that [illegible] from December 28th Two days later two children belonging to a second family became ill and were put to bed [illegible] The rash was in a period of seven days when examined [illegible] 10th and children [illegible] the rash appeared [illegible] December 27th [illegible] from [illegible] Afterwards [illegible] with [illegible] of [illegible] Nowegian [illegible] [illegible] [illegible]

Proportion of Rent etc for Professional Use

B N used to be allowed two thirds and later one half of the rent and similar expenses incurred by him as applicable to his professional use of his premises Recently the inspector of taxes has contended that one third would be sufficient

*** This is one of those questions where so much turns on the precise circumstances of each case that advice is difficult and may be misleading On the face of it one third hardly seems adequate especially if the waiting and consulting rooms are not used privately and if the total rent covers the use of a garage for the professional car Two points which may be mentioned are (1) that the ground floor has a much larger rental value than any other and (2) that a fair test of the proposed professional proportion can sometimes be obtained by comparing the amount of the balance left for private use with the actual accommodation available and the probable cost of that accommodation in the immediate neighbourhood

Assistant Tax not Applied for

A P M N has been in receipt of emoluments sufficient to create liability to tax since 1928–29 inclusive but has not received any income tax demand How does he stand legally and what should he do?

*** The emoluments are assessable (Schedule E) and there is no legal liability to make a return under that schedule until called upon to do so by a notice served on the recipient of the emoluments When the liability comes to light however as presumably it will sooner or later—for example through the accounts or statutory returns of the employer— A P M N will be assessable for the then current and the six preceding years On the whole it would seem desirable on general grounds for A P M N to inform the local inspector or collector of taxes that he is receiving a taxable salary if neither of them then raises the question of earlier years having regard to the voluntary disclosure so much the better for our correspondent

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

29 Aneurysm of the Wall of the Heart

A. C. ALVAREZ (*Arch. des Mal. du Coeur*, August, 1931, p. 465) has made a clinical study of the development of an aneurysm of the wall of the left ventricle. The patient, a syphilitic man aged 53, had for a month experienced pain in the chest which spread down the left arm on effort. No physical signs of heart disease were present, and the orthodiagram and blood pressure were normal. He then had a severe cardiac infarction, accompanied by the usual fever and leucocytosis, and by a reduction of the pulse rate to 30. Within a week pericardial friction appeared, and a fortnight later localized bulging of the border of the left ventricle was observed on x-ray examination. A period of gradual improvement followed during the next month, but at the end of this time congestive failure set in, while an x-ray investigation showed progressive enlargement upward and to the left of the left ventricle. Sudden death probably by rupture terminated the illness. The author remarks that although in this case radiography clinched the diagnosis, in some cases an aneurysm at the apex is obscured by the shadow of the diaphragm. Reference is made to the stages of evolution described by Sternberg: the onset of inguinal attacks followed by signs of pericarditis, then a latent period of apparent cure, and finally serious cardiac insufficiency. In the case described the phase of pericarditis belonged rather to the first stage, while the third and fourth stages were well marked. The author remarks that patients suffering from cardiac infarction without aneurysm of the heart may show exactly the same sequence of clinical manifestations. The swift evolution of aneurysm of the heart, as in the author's case, is specially apt to be followed by perforation, while those aneurysms which develop very slowly are supported by pericardial adhesions and seldom rupture.

30 An Epidemic of Chicken-pox in Spitzbergen

J. FRIIS (*Tidsskrift f. d. Norske Laegefor.*, October 1st, 1931, p. 797) gives an account of an epidemic of chicken-pox which throws some light on the problems of its source and incubation period. In a colony of about 500 persons, including about 40 children, in the coal-mining settlement in Advent Bay in Spitzbergen, which is completely cut off from the rest of the world for seven to eight months in the year on account of darkness and ice, an epidemic of chicken-pox broke out at the end of December, 1930, in a family with four children. The date on which the last boat had left for Norway was October 21st. Three of the four children showed the characteristic chicken-pox rash in various stages of development when first examined on December 29th. The mother had noticed a rash on December 27th, but had taken the children to a Christmas party on this date. Spread of the infection was therefore to be anticipated, although the first three patients were isolated from December 29th. Two days later two children belonging to a second family became ill and were in their turn isolated. There was now an interval of eleven days *without any new cases*. From January 10th and during the following week eleven new cases cropped up, and if it is assumed that they were all infected on December 27th, the incubation period ranged from 13 days in the earliest case to *21 days in the latest case*. After a free interval of five days there was a third crop of new cases with an incubation period of 12 to 13 days. The children who first *became ill had come* from Norway on September 24th, and *it seems highly* improbable that they had been infected *before this date*. The children who fell ill in the second family had not been in Norway since the summer of *1928*, and *it is* therefore probable that the source of the original infection must have been in Advent Bay itself. Since the author took medical charge of the colony in June, 1930, three cases of herpes zoster came to his notice, the first developing on August 28th, and the second one day before the last two cases of chicken-pox developed. A case of herpes labialis occurred on September 22nd, and another on October 13th.

31 Post-vaccinal Encephalitis in Holland

According to N. M. J. JITTA (*Bull. Office Internat. d'Hyg. Publ.*, October, 1931, p. 1804) from 1924 to May, 1931, 836,100 vaccinations were performed in Holland and were followed by 186 cases of encephalitis, which is equivalent to 1 case of encephalitis to every 4,656 vaccinations. A special commission appointed to examine each case classified them in four groups—namely, (1) undoubted cases, (2) almost undoubted cases, (3) doubtful cases, and (4) very doubtful cases. In the statistics drawn up by the Inspector-General only the first two groups were considered. Among about 62,000 children vaccinated in the first year of life there were only three cases of encephalitis, and among 137,000 children between the ages of 1 and 2 years only five cases, or one case among 25,000 vaccinations in children under 2 years of age. All these patients recovered without sequels. Among 660,000 children between 2 and 11 years there were 159 cases, or 1 in 3,570. 55 of these died, a proportion of one death to 15,749 vaccinations. In 1930, 5 cases occurred among 27,131 vaccinations, or one case among 5,426 vaccinations. There has been a great decline in the number of vaccinations after the small outbreak of small-pox in the second half of 1929, and as compulsory vaccination at school age has been temporarily suspended no case has occurred since May, 1930, and May, 1931, although between 24,800 and 25,000 vaccinations were performed during that period.

32 Influenzal Parotitis

M. VILLARET and GUILLAIN (*Gaz. des Hop.*, October 21st, 1931, p. 1563) record three cases of influenza in adults complicated by suppurative parotitis and pulmonary congestion. The pus in each case contained pneumococci in large quantities, associated in one instance with staphylococci. Two of the patients made good recoveries, but the third died a month after his discharge with symptoms of acute pulmonary tuberculosis which had supervened on the attack of influenza.

Surgery

33 Arterial Resection in Arteritis Obliterans

R. FONTAINE (*Bull. et Mem. Soc. Nat. de Chir.*, October 24th, 1931, p. 1184) reports a case of obliterative arteritis in both lower limbs in which cure followed resection of the femoral arteries. This is considered further proof that an obstructed artery can be resected without hesitation, and that the operation should be performed when vasomotor troubles exist in the periphery of the limb. By this procedure an ideal resection of a disordered sympathetic plexus, the cause of the peripheral trouble, is actually performed. During the war Leriche advocated resection in cases where the arterial trunks had been destroyed and sclerosed by wounds. Discussing this case, Moure states that resection of permeable vessels or of those recently thrombosed is of slight use, and that favourable results can be obtained only if the peripheral circulation remains permeable. He believes that the good effects are due not only to a suppression of the periarterial sympathetic, but also to an arrest of the thrombosing process.

34 Septic Cavernous Sinus Thrombosis

B F STOUT (*Journ Lab and Clin Med* October 1931 p 28) believes that acute infectious cavernous sinus thrombosis is possibly more common than the few cases reported indicate and records two further cases In one of these recovery ensued, it is particularly interesting since it indicates the possibility of recovery in this condition with septicaemia and meningitis the possible sterilization of a heavy blood infection by intravenous bacteriophage therapy and the control of a staphylococcal meningitis by intraspinous bacteriophage injections The Schilling index also faithfully indicated the clinical facts The starting point of the disease in both cases was a small facial furuncle Staphylococci were isolated from the blood and lesions In the case of the patient who recovered the bacteriophage was first administered locally and subcutaneously then intravenously and finally intraspinally Stout believes that this patient survived because of the early and vigorous treatment and that the other patient who was in a hopeless condition when first seen might also have recovered if similarly early treatment had been possible Success in the one instance shows the possible efficacy of this treatment in staphylococcal septicaemia from other foci The bacteriophage in association with any necessary surgical measures should be used locally subcutaneously and intravenously Single doses up to 5 c cm can be given subcutaneously and 1 to 2 c cm doses intravenously with safety

35 Cholecyst gastrostomy in Ulcer

It is claimed by some authors that cholecyst-gastrostomy, by introducing a constant flow of bile into the stomach prevents or hinders ulcer formation others have shown that free hydrochloric acid and normal peptic digestion may continue despite this operation A case of anastomotic ulcer and another of perforation following cholecyst gastrostomy have been recorded P WALZEL (*Zentralbl f Chir* October 24th 1931 p 2679) records the case of a man aged 32 in whom abdominal pain and obstructive jaundice suggested pancreatic carcinoma An operation revealed enlargement of the pancreas which was thought to be malignant with complete obstruction of the bile duct and dilatation of the gall-bladder A cholecyst gastrostomy was performed and also a gastrojejunostomy with entero anastomosis since the swelling appeared to be invading the duodenum The jaundice disappeared and the patient recovered Two and a half years later he complained of pain in the upper part of the left side of the abdomen A test meal showed bile stained stomach contents the free acid figure was 27 and the total acid figure was 54 A second operation was performed at which a large perforating peptic ulcer was found at the site of the anastomosis The cholecyst gastrostomy condition was working perfectly the pancreas was still enlarged and completely occluded the bile duct A partial gastrectomy was successfully performed The case is considered by Walzel to be of particular interest since there was no doubt about the correct functioning of the cholecyst gastrostomy or that the ulcer developed after that operation had been performed

36 Tumours of the Suprarenal Gland

J MEYER and G TRUMESS (*Arch Int Med* October 1931 p 611) discuss tumours of the suprarenal gland with special reference to carcinoma of the cortex They report the case of a girl aged 13 who complained of pain in the chest and abdomen and had an acneform dermatitis of the face and trunk of about five months duration with indigestion epileptiform attacks and cessation of the menses Well developed and nourished she appeared to be older than her age she had a negroid facies which was accentuated by hirsuties The liver was increasing in size and the epigastric fullness and pain became worse one week after admission there was rapid exacerbation of the symptoms intra abdominal haemorrhage and subsequent death The pubic hair was abnormal in growth with a distinct tendency to masculine distribution At the post mortem examination a large primary carcinoma of the left suprarenal gland was found with metastases in the pleurae and liver, and the formation of peritoneal and mediastinal nodes The sexual alterations produced in the female by hypertrophy of the suprarenal cortex proceed towards the adult male type they are accompanied by enlargement of the clitoris atrophy of the uterus and breasts amenorrhoea abnormal growth and masculine distribution of the pubic hair, with loss of erotic feelings and of the sense of modesty The prognosis depends upon the character of the growth the degree to which it has infiltrated adjacent structures and the extent and accessibility of its metastases Successful removal has been effected in three cases with complete return of the sexual characteristics to normal

Therapeutics

37 Iron Cacodylate in Acute Bursitis

Unexpected good effects on a bursitis in a patient who was being treated for boils with injections of iron cacodylate led T K RICHARDS (*New England Journ of Med* October 22nd, 1931 p 812) to try this method on other patients Accordingly this treatment was given to approximately 70 cases of acute bursitis subacromial subscapular and infrapatellar The salt was injected intravenously with striking results immediate lessening of the acute symptoms occurred within three to four hours after the first injection and most of the patients were able to resume their normal activities in ten to twenty one days Both iron arsenite and cacodylate have been tried but the latter salt is preferred since it causes less severe reactions The initial dose is not more than 3 c cm (3/5 grain) of the cacodylate on the third or fourth day 5 c cm (1 grain) are given and this dose is repeated every three or four days until the symptoms have disappeared While there was no radiological evidence that the absorption of lime deposits in the bursae was hastened Richards believes that this method surprisingly relieves the acute symptoms by making the movements painless it prevents the formation of periarticular adhesions and thus averts distressing complications Three case histories illustrating the effectiveness of this treatment of bursitis are appended

38 Treatment of Early Syphilis

V C GARNER and J H STOKES (*Med Journ and Record* October 21st 1931, p 369) believe that the effective treatment of early or acute syphilis must comprise the prolonged simultaneous administration of an arsphenamine and a heavy metal given in a conservative dosage, and without any rest intervals They ascribe failures in efficiency to the fact that such smoothness of treatment has not been secured The medical practitioner is not generally familiar with the therapeutic shock or Herxheimer reaction he aerates (and thereby renders toxic) neoarsphenamine in its preparation and insists upon its speedy administration thereby provoking complications The authors prefer bismuth arsphenamine sulphate (bismarsen) which contains 23 to 25 per cent bismuth with 12 to 15 per cent arsenic it is given as intramuscular injections There is said to be no therapeutic shock reaction and fewer complications ensue in the skin and viscera than accompany intravenous administration A dose of 0 2 gram is given twice a week to a total of forty to sixty injections followed immediately by two or three courses of bismuth the rest interval being omitted with a consequent 5 per cent diminution of the incidence of relapse The authors add that if sulpharsphenamine is employed it should be injected only into the muscles Its use seems definitely associated however with a greater incidence of exfoliative dermatitis and with the fatal complication of aleukaemia haemorrhagica They urge that the conception of the short abortive course for cure when the infection is detected in the sero negative primary stage is no longer tenable A spinal fluid examination is essential between the sixth and twelfth months of treatment and even if completely negative as regards the cell

count Wassermann reaction presence of globulin and the colloidal curve should not prevent the treatment being continued for at least one year from the time when the blood became finally Wassermann negative

39 Neosalvarsan in Psoriasis

M G ROSENBAUM (*Derm Woch* October 31st 1931 p 1697) records two illustrative cases of obstinate psoriasis in a man aged 48 and a woman aged 27 in each case the disease had lasted for many years but recovery ensued in a few weeks after three injections of neosalvarsan He alludes to the work of older writers especially the British dermatologists Erasmus Wilson Taylor and Anderson who held that psoriasis was a late and modified form of syphilis Although such a view is now considered to be quite unfounded arsenic is still regarded by many authorities as the sovereign remedy for psoriasis and Rosenbaum concludes that the excellent results obtained from the use of neosalvarsan afford corroboration of this view

Disease in Childhood

40 Juvenile Nephrosclerosis

Using the term nephrosclerosis A G MITCHELL and G M GUEST (*Journ Amer Med Assoc* October 10th 1931 p 1045) record a study of chronic interstitial nephritis in childhood Owing to the lack of sufficiently accurate data the etiology of the condition is difficult to define A familial and hereditary predisposition is present intrauterine renal disease or nephritis in very early life may occur Acute bacterial infections especially streptococcal may cause renal injury resulting in chronic disease but a history of previous infection is no proof that chronic nephritis is its direct sequel Syphilis focal infections and exogenous and endogenous poisons are seldom etiological factors High protein diets are not causative agents hence too great protein restriction in children is not warranted and their diet should meet the usual normal requirements The symptomatology and examination of nephrosclerotic children are summarized many of the symptoms and signs are the same as in adults Of special interest are the peculiar bone changes simulating infantile rickets which occasionally arise and the undernutrition and dwarfism which commonly accompany chronic renal disease in childhood The authors consider that further studies of the total mineral metabolism are necessary to explain these disturbances

41 Cardiac Changes caused by Diphtheria

C SHOOKHOFF and L M TARAN (*Amer Journ Dis Child* October 1931 p 811) made electrocardiographic studies of 50 children aged from 5 to 14 years during the course of mild diphtheria with the following results The average cardiac rate was found to be higher than in normal children or in children with scarlet fever of the same age group 56 per cent of the patients showed sinus arrhythmia No abnormal prolongations of the P–R interval were observed In 16 per cent a slurring of the descending limb causing a widening of the QRS time was noticed indicating disturbance in the intraventricular conduction 46 per cent of the children with abnormalities in the ventricular portion of the electrocardiogram showed a persistence of these symptoms up to the time of discharge Only seven of the children who showed abnormalities in the electrocardiogram indicating myocardial disease presented clinical symptoms of such involvement The authors conclude therefore that children convalescing from diphtheria should not be pronounced out of danger without such an investigation Electrocardiographic abnormalities in diphtheria are similar to those in scarlet fever in the following points they occur in a high percentage of even mild cases they tend to persist and they may be found in the absence of clinical signs of myocardial involvement They differ however in the absence of disturbance in the auriculoventricular conduction in mild cases

42 Bronchiectasis in Children

G RULLIE (*Bruxelles Medical* October 4th 1931 p 1427) maintains that this condition is more common than is generally believed it follows the subacute bronchopneumonias which complicate measles influenza and especially whooping cough He describes three cases in children aged 4 9 and 13 years respectively The features common to them all were the good general condition of the child the absence of fever and of tubercle bacilli in the sputum with the presence of pulmonary sclerosis and of the classical pulmonary signs Dullness and moist sounds are most often present at the base but may be detected higher up or in the axilla Characteristically the signs vary from day to day The moist abundant and coarse rales indicate bronchial dilatation diminution of the respiratory murmur is the sign of pleural thickening and thoracic retraction of pleural adhesions From time to time there may be an exacerbation due to a simple coryza or to some intercurrent malady Radiography after the intratracheal injection of lipiodol confirms the diagnosis this may induce a temporary deterioration of the condition The treatment comprises sunlight and pure air the administration of balsams ergotin and strychnine the institution of remedial exercises and the injection of autogenous vaccines Artificial pneumothorax has been very successful in some cases but must not be left until too late when the pleural thickenings and adhesions have become marked

43 Hypotension in Childhood

F GIERTHMUHLEN (*Munch med Woch* November 20th 1931 p 1957) states that the blood pressure in childhood is lower than in adult life owing to the relatively small size of the child's heart the width of the vessels and their lack of resistance In the newborn the average systolic pressure is 43 mm this rises to 80 mm at the end of the first year and increases by 2 mm each year up to puberty It then rises more rapidly until it reaches the normal adult level between the 16th and 18th year Systematic examination of about 200 school children aged between 10 and 11 years showed that while the majority had a systolic pressure of about 100 mm Hg in a certain number it was between 75 and 60 mm In some of these children the hypotension was found to be due to tuberculosis but the majority appeared to be perfectly healthy although they showed evidence of an asthenic constitution indicated by pallor and lack of muscular tone Such symptoms need give rise to no anxiety since the expectation of life in these children is good but the essential hypotonus can be effectually treated by ultraviolet light and the administration of atropine and strychnine

Obstetrics and Gynaecology

44 Diathermy in Gonococcal Infections

B F BOLAND (*New England Journ of Med* November 5th 1931 p 903) discounts the value of diathermy in active gonococcal infections of the female genitalia though it is useful in latent cases such as chronic endocervicitis where smears are negative as a means of stimulating the cervical discharge Moreover it is a helpful adjunct to the treatment of inflammation of the glands of Skene and Bartholin He records a series of investigations in which it was shown that one exposure to diathermic heat of 110° to 113° F did not kill the gonococcus while through and through body heating did not raise the uterine temperature to over 100° F Although some patients received ten or more cervical applications the cultures taken subsequently remained positive Boland adds that the correct diagnosis must be established before any form of diathermy is tried Pregnancy must be considered a contraindication in view of the risk of abortion Excessive local heat will also cause haemorrhage if a fibroid is present An acute inflammation which is just subsiding will flare up again if heat is applied too early

45 Cervical Caesarean Section

J P GREENHILL (*Surg Gynecol and Obstet* October 1931 p 547) records a series of 108 consecutive cervical Caesarean sections and 9 Porro operations after laparo trachelotomy in which there were no maternal deaths Of these patients 58 were primiparae and 59 were multiparae The chief indications for the operations were disproportion of the pelvis and foetal head 47 per cent previous Caesarean section with test of labour 6 8 per cent previous sections without test labours 12 8 per cent toxaemia without convulsions 7 7 per cent eclampsia 1 7 per cent placenta praevia 6 per cent placental detachment 4 3 per cent cardiac disease 4 3 per cent and the dystocia dystrophia syndrome 3 4 per cent The membranes were ruptured in 26 5 per cent of the cases at the time when the operation was performed and the time interval ranged from half an hour to seventy-one hours Direct infiltration anaesthesia alone was used in 64 1 per cent of all cases in an additional 6 8 per cent a general anaesthesia was associated with local anaesthesia ether was employed in 24 8 per cent and ethylene was given in 4 3 per cent A temperature of 100° F or more was noted in 49 6 per cent of the cases due to such conditions as infected wound (9 6 per cent) pyelitis and cystitis (5 1 per cent) and bronchitis (2 6 per cent) In 59 8 per cent of the cases the patients left the hospital within 14 days and in 83 8 per cent within 18 days The total foetal mortality was 4 3 per cent but three of the five deaths occurred before the operation was performed In most instances the wounds of the cervical Caesarean sections healed very well as was proved by the microscopical examination of pieces of scar tissue removed at the time of repeated laparo trachelotomies

46 Dental Extractions in Pregnancy

MARTINAUD (*Journ de Med de Bordeaux* October 10th 1931 p 840) states that dental extractions can and should be undertaken in pregnant women when desirable There are very few exceptions to this rule When possible a local or regional anaesthetic should be given Adrenaline has some action on the uterine muscle but is not necessarily contraindicated Septic conditions of the mouth and teeth constitute a more serious risk to the normal progress of pregnancy than does a surgical operation which is in itself benign Even a general anaesthetic can be employed without hesitation

Pathology

47 The Suprarenal Glands in Fatal Burns

S G BERKOW (*Med Journ and Record* October 21st 1931 p 386) discusses the part played by the suprarenal glands in connexion with the symptoms and late death from extensive superficial burns Excision of both glands in animals has been shown to produce asthenia hypotension loss of body heat glycosuria acute gastric and duodenal ulcers and sudden death after a latent period of apparently satisfactory progress Such adrenalectomized animals react in a characteristic manner not observed in any other condition except that which ensues after extensive burns and scalds of the skin The cause of the sudden onset of fatal symptoms resulting from suprarenal insufficiency is not known but a plausible theory appears to be that the initial shock in cases of extensive burns and scalds stimulates an outpouring of the suprarenal medullary secretion which is responsible for the alertness and lack of clinical evidence of shock so often seen after such extensive injuries Congestion and haemorrhage into both the cortex and medulla almost immediately follow the resulting interference with their function being responsible for the predominant symptoms which occur later The actual way in which such suprarenal insufficiency acts is unknown although the relative importance of the cortex and medulla is obscure the view predominates that the cortex is the more essential to life Berkow considers that treatment by the oral administration of whole suprarenal gland or the hypodermic injection of suprarenal medullary extract has been sufficiently encouraging to warrant more extensive clinical trial being undertaken

48 The Sedimentation Test in Surgical Tuberculosis in Children

S HARILD (*Ugeskrift for Laeger* October 1st 1931 p 987) states that at the Surgical Department of the Finsen Institute in Copenhagen the rate of sedimentation of the erythrocytes has been investigated during the past two and a half years in all the out patient as well as in patient cases In 41 cases of uncomplicated tuberculosis of the bones and joints of children between the ages of 2 and 14 the sedimentation test was performed 106 times In a group of 12 cases there were as many as 6 in which the test and the clinical evidence were at variance the former being normal while the latter indicated active tuberculosis It would seem therefore that the sedimentation test is of no value in the diagnosis of diseases of the bones and joints for not only may a normal test be associated with active tuberculosis but an increased rate of sedimentation does not in itself necessarily indicate the presence of tuberculosis In the course of treatment however the behaviour of this test may in conjunction with the clinical evidence be helpful and the test is of some prognostic value It is nevertheless far from being so reliable that its evidence can be the basis for deciding when to discharge a patient from hospital

49 The Destruction of Br abortus in Milk and Cheese by Lactic Fermentation

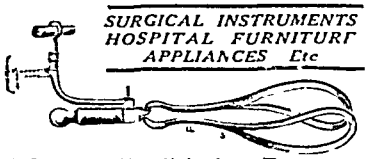
P MAZE and E CLSARI (*C R Soc de Biologie* November 13th 1931 p 610) report experiments made to ascertain the longevity of *Br abortus* in milk and cheese which are undergoing lactic fermentation A thick suspension of *Br abortus* was made in sterilized milk which was then inoculated with a small quantity of a lactic ferment commonly used in cheese manufacture The ferment developed normally and coagulated the milk at laboratory temperature in 24 hours the acidity at the end of 48 hours was equivalent to 0 9 per cent lactic acid—the same value as in control cultures containing no *Br abortus* Starting from 48 hours after the commencement of the experiment subcultures were made from suitable dilutions on to Martin's agar medium Colonies of the lactic ferment appeared in 24 hours colonies of *abortus* did not become visible for five days Three sets of observations were made in which the number of *abortus* to the number of lactic organisms was about 50, 500 and 5 000 All three experiments gave the same results *Br abortus* was killed by the acid in the medium in less than 48 hours from the time of inoculation Since cheeses made in this manner are not consumed for five or six days after the original inoculation of the milk the authors conclude that there is no danger of *abortus* infection occurring from their consumption Other workers have obtained more or less similar results with Roquefort cheese made from ewe's milk and with Saint Marcellin cheese made from goat's milk in these cheeses *Br melitensis* lives only five days

50 Purulent Infection with B influenzae

E WAALER (*Norsk Mag f Laegevid* July 1931 p 715) records two cases of pyogenic infection due to Pfeiffer's *B influenzae* The first patient was a male infant aged 20 months who was taken ill with symptoms of a feverish cold and later developed a painful swelling of the left knee joint and symptoms of meningitis Death took place a month after the onset A pure culture of *B influenzae* was obtained from the pus in the knee joint and also from the blood The second patient was a male adult who had suffered from inflammation of the nasal sphenoidal and ethmoidal sinuses for the last fifteen years An almost pure culture of *B influenzae* was obtained from the nasopharynx A favourable result followed treatment by anti catarrhal vaccine

BISEDIA

A combination of Schacht's pure Bismuth and Pepsina Liquida with Sedatives ..



Gives excellent results in the treatment of Acute Dyspepsia, Gastric Ulceration, Vomiting of Pregnancy and Gastric Hyperasthenia.

Samples and literature will be willingly supplied to medical men by the manufactuers

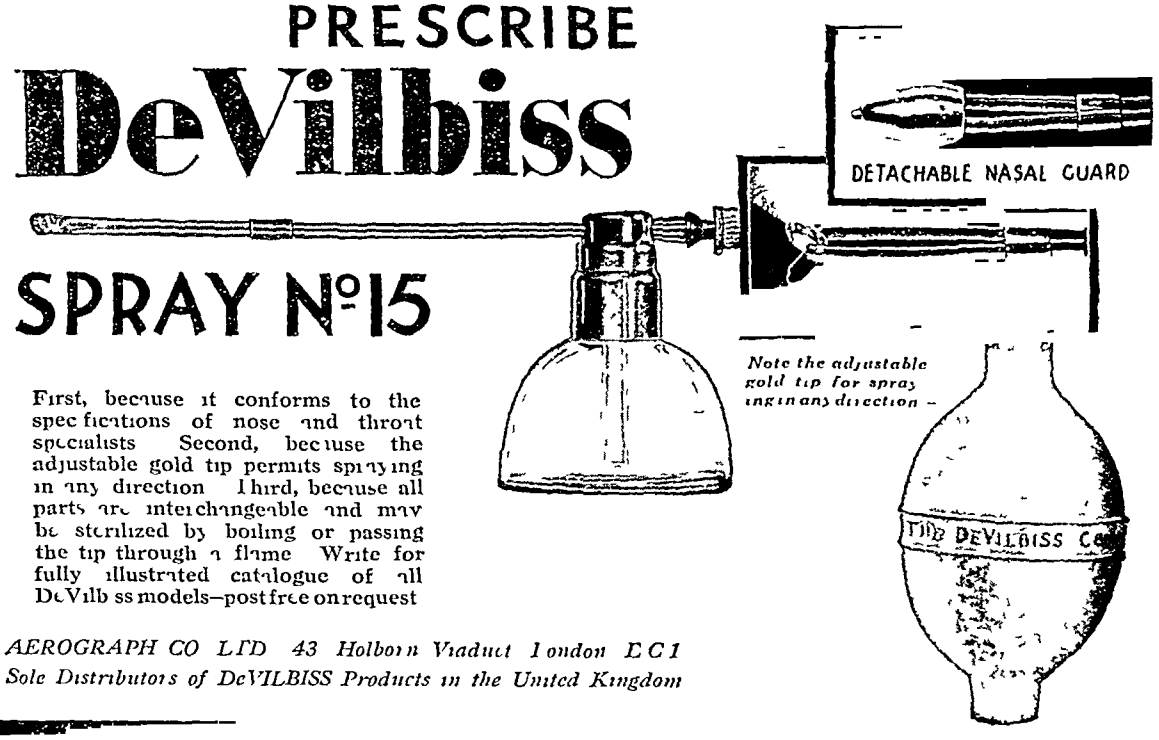
BED DAMPNESS BANISHED . . . .

An important health factor, particularly at this time of the year when coughs, colds, and flu are so prevalent, is sound healthy sleep

Thermega Electric Blankets and Pads are made for this specific purpose

Laid flat on the bed and switched on an hour before retiring, the Blanket airs and warms the bed to body temperature The Pad ensures LOCAL regulated heat which may be maintained as long as desired

Both are controlled by an ordinary wall switch (any voltage, 100—250), overheating is eliminated by special thermostatic control, current costs less than a farthing an hour



Blankets from £3 3s , Pads from 31/6d , Heating Blankets for Doctors' couches from £7 Special appliances for pneumonia, operations, etc , to order

Further details supplied immediately on request

Individuality in Trusses.

The section of our Surgical Service relating to the supply of Trusses has a world wide reputation for Efficiency

This success is due, in our opinion to our knowledge in correctly interpreting the attendant practitioner's instructions and also to the fact that every Truss we supply is 'individual' in the true sense of the word

We keep a stock of several thousands of hand made springs of varying gauges and tempered to different strengths in addition we have a large variety of sizes and shapes in pads From these component suitable springs and pads are chosen exactly to conform to the Medical Man's orders, the truss is then assembled and covered as required

In all cases our aim is to make an Individual Truss for each patient, suitable in Fit, Quality,' and 'Price'

EDUCATION and ENDOWMENT

To Parents—

You desire, naturally, that your children shall receive a good sound education to fit them for life among their fellows

Education costs a lot of money—quite a lot—and the future may be uncertain Let us tell you how the cost can be met by provision under an Educational Endowment Assurance Even should you die the moneys required will still be forthcoming

Then, you ought to do something more for him or for her You want to make sure they can have Life Assurance when they grow up

At a cost of £10 a year you can secure for them quite a nice policy on their coming-of-age giving them protection even should they not then be first class lives—and so otherwise uninsurable

You may do even more, you may help the Guild to educate the children of people who are less provident and far-sighted than yourselves—at no cost to yourself

The **Medical Insurance Agency** will be pleased to tell you all about these schemes if you will send a note of your own age and the ages of the children (next birthday) to —

ENGINEERING PROBLEMS IN ABDOMINAL DISPLACEMENTS SOLVED BY SURGICAL BELTS

The medical profession is beginning to realise that when it is a matter of internal displacement, abdominal disorders will not yield the stimulation or lubrication from within These methods ignore the mechanical problems which would be the first consideration of an engineer called upon to conserve the function and structure of a coiled, mobile and valved tubing such as the alimentary system The solving of these problems is the first consideration in the construction of Domen Belts

These Belts correct and prevent mechanical faults in the engineering system of the abdomen by counteracting with upward support the downward pull of gravitation And to do this Domen Belts rest upon the only anatomically legitimate foundation—the bony pelvis Domen Belts are designed for specific complaints They fit well and comfortably They leave the patient free and unembarrassed Your card or a telephoned request will bring you full particulars

ROYAL ARMY MEDICAL CORPS.

TWENTY FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in January, 1932 Applications should reach the War Office not later than January 18th, 1932.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January They must be under 28 years of age on February 1st, 1932, and registered under the Medical Acts

Officers of the R A M C are liable to serve in any part of the world where British Troops are quartered

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches

The cost of Post-Graduate study, which is compulsory, is met from Army Funds

Pay and Allowances—From £476 to £2,000 a year according to rank and length of service

Candidates who have held a full-time house appointment in a recognised civil hospital before appointment to a permanent Commission in the R A M C may, subject to certain conditions, be allowed to count the period of service in such an appointment, up to a maximum of 12 months, as Army service for promotion and increase of pay

Gratuities on Retirement.—After 7 years' service £1,000
„ 15 „ „ £2,800
„ 18 „ „ £3,500

Current rates of retired pay range from £352 10s per annum normally earned by a Major after 20 years' service, to £890 per annum, the maximum for which a Major-General is eligible The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living

Outfit Grant—An officer on joining receives £50 as outfit allowance.

Marriage Allowances—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A M D 1), Whitehall, London, S W 7

Starch in Infant Feeding

Microphotograph of iodin stained faeces of infant fed on starchy food

Microphotograph of normal faeces of breast fed infant

Starch is never found occurring in any type of milk the infant's digestive tract is not equipped for the absorption of starch during the first seven months The addition of starch to the diet of such children makes unjustifiable demands on its alimentary canal and by disturbing the normal ratio of proteins carbohydrates, fats and vitamins prepares the ground for rickets and scurvy Formerly such addition was recommended on the ground that casein was thereby rendered more digestible The Improved Roller Process employed in the manufacture of COW & GATE Milk Food modifies the casein and renders it so digestible that the curd is as fine and flocculent as that of breast milk Moreover the old fashioned method of adding starchy products to raw milk carries all the risks inherent in the use of raw milk with the ever-present danger of tuberculosis and all the other infections carried by raw milk On the other hand COW & GATE is 200 times cleaner than Certified milk, is unvarying in composition and is the safest and most suitable substitute for natural feeding from birth to seven months As an introduction to mixed feeding at the seventh month PEPTALAC the Cow & Gate Predigested Milk Wheat Food is strongly recommended 25% of its starch content is predigested and it has the overwhelming advantage over all other starch preparations employed in infant feeding usually very low in fats of a normal fat percentage It is simply prepared by the addition of water

Cow & Gate Milkfood

Clinical samples of Cow & Gate and Peptalac will be gladly sent on request to any member of the Medical and Nursing Professions

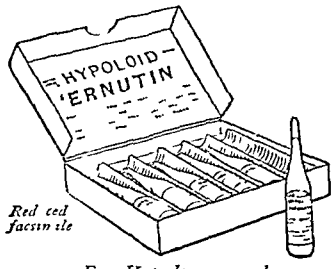
COW & GATE LTD. GUILDFORD, SURREY

Ergotoxine Ethanesulphonate

Used in the preparation of

TRADE 'ERNUTIN' MARK

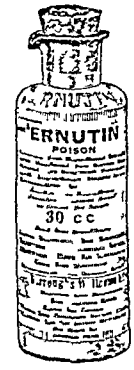


A clear solution presenting Ergotoxine (the specific active principle of the official Ergot), together with 'Tyramine' and 'Ergamine,' in definite amount and in a state of chemical purity

Used with consistent success in obstetrical practice to induce contraction of the uterus after labour

The Ergot Sub-committee of the Pharmacopœia Commission recommend that ergotoxine be included in the new British Pharmacopœia in the form of ethanesulphonate, because

(1) It would furnish the definition of the standard to be used in the assay by colour test,



(2) It is a suitable salt for hypodermic use, to replace Hypodermic Injection of Ergot

Reduced facsimile

For Hypodermic and Intramuscular Injection

'HYPOLOID 'ERNUTIN in boxes of six hermetically sealed containers of 0·6 c.c. (approx. min. 10) of *Sterile* Solution, at 3/4 per box

Reduced facsimile

Ergotoxine Ethanesulphonate was originated and introduced by Burroughs Wellcome & Co

'ERNUTIN' (Oral) contains 0·033 per cent and 'HYPOLOID' 'ERNUTIN' 0·1 per cent of Ergotoxine Ethanesulphonate

WELLCOME' ERGOTOXINE ETHANESULPHONATE

Supplied in tubes of 0·1 gm at 7/9 each

For Oral Administration

'ERNUTIN' (Oral), in bottles of 30 c.c. 4 fl. oz. and 16 fl. oz. at 2/6, 7/6 *and* 25/ each, respectively

Prices quoted are those in London to the Medical Profession

reasons for prescribing

ANTIPHLOGISTINE

BRAND DRESSING

in

Pneumonia

1. ***Analgesic:*** It relieves pleuritic pain;
2. ***Resolvent:*** It favours resolution,
3. ***Relaxant:*** It relaxes the muscular and nervous systems, thus ensuring ease and comfort to the patient

Applied as a jacket over the entire thoracic wall, Antiphlogistine Dressing will do much to promote rest and sleep, which are essential for sustaining the vitality of the patient

AN INDEX OF PROGNOSIS

AND END-RESULTS OF TREATMENT

Edited by A RENDLE SHORT, M D , B S , B Sc Lond , F R C S Eng ,
Hon Surgeon Bristol Royal Infirmary

IN CONJUNCTION WITH 27 SPECIAL CONTRIBUTORS

Sets forth the results and particularly the end results of various methods of treatment in such a form as will enable the practitioner to obtain a fair unbiased reasoned opinion as to the prospects of securing for his patient permanent relief and the risks of such treatment It also furnishes data by means of which apart from the question of treatment one may arrive at an accurate forecast of what will probably happen to the individual patient

To day when methods of treatment have multiplied it is more than ever desirable that the doctor whether he be general practitioner or specialist should have some such guidance as this so that he may choose the better and refuse the worse

We have formed a high opinion of the value of the Index of Prognosis *and desire to commend the work to our readers as one which they would do well to place upon their bookshelves* —BRITISH MEDICAL JOURNAL

Everything to look for on a Bottle..

IMITATION may be the sincerest form of flattery, but the extent to which the U G B Medical Bottle is imitated in inferior quality is far from gratifying

Designed some ten years ago as an ideal dispensing bottle, it is now the standard for this purpose The consistently high quality, accurate capacity and attractive appearance, places the U G B Medical in a class by itself.

The success of this bottle has been greatly enhanced by the introduction of the "WASHED & STERILIZED READY-TO-USE BOTTLE" packed in non-returnable Dustproof Solid Fibre Cartons—supplied either for Corks or complete with Rustless White Enamelled Screw Caps

Obtainable from all leading Wholesalers

Education and Endowment

To Parents—

You desire, naturally, that your children shall receive a good sound education to fit them for life among their fellows.

Education costs a lot of money—quite a lot—and the future may be uncertain Let us tell you how the cost can be met by provision under an Educational Endowment Assurance Even should you die the moneys required will still be forthcoming.

Then, you ought to do something more for him or for her. You want to make sure they can have Life Assurance when they grow up.

At a cost of £10 a year you can secure for them quite a nice policy on their coming-of-age, giving them protection even should they not then be first-class lives—and so otherwise uninsurable.

You may do even more, you may help the Guild to educate the children of people who are less provident and far-sighted than yourselves—at no cost to yourself.

The Medical Insurance Agency will be pleased to tell you all about these schemes if you will send a note of your own age and the ages of the children (next birthday) to —

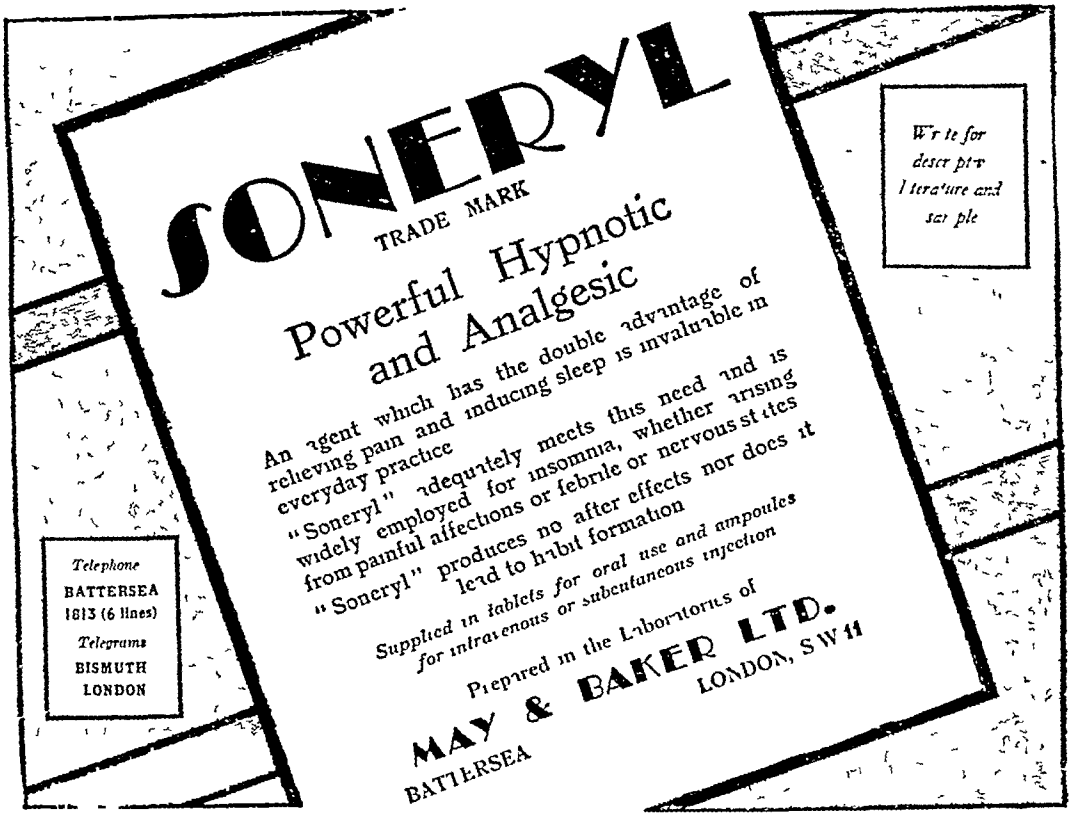
When the buffer bodies are depleted

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions

as in acidosis, acidemia and their correlated pathological disturbances, rational alkaline medication is essential

Alka-Zane containing alkaline salts in proportions adapted to the physiological requirements of the body, promptly corrects hyperacidity, promotes diuresis and the restoration of the all-important alkaline reserve



A trial will demonstrate the outstanding merits of

ALKA-ZANE

PROTEIN FEEDING

The peptised vegetable proteins in Mellin's Food perform a dual function in metabolism

1 By substantially increasing the supply of essential amino-acids tyrosine, lysine, tryptophane

2 By their buffer actions they lower the pH of the milk mixture and thus assist in fat emulsification and prevent the formation of heavy casein curd

Milk modified by Mellin's Food is easily digested and quickly absorbed

Mellin's Food

prevents the appearance of curdy stools

Samples and booklet containing full details of composition and calorific value of mixtures suggested for different ages and conditions post free from —

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

Alasil completely overcomes this objection By combining calcium acetyl salicylate with Alocol unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of Alocol (Colloidol Hydroxide of Aluminium) which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract Alasil is therefore a triumph over acetyl salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic Antipyretic and Sedative Alasil is indicated in all cases where acetyl salicylic acid has been used heretofore

A supply for clinical trial with full descriptive literature sent free on request

. . . the treatment of
ONYCHIA and PARONYCHIA

● *Practitioners are invited to apply for particulars and clinical sample to the manufacturers*

In certain industries, as has been recently emphasised in the medical press, occupational diseases of the finger-nails are extremely common Such diseases are usually most intractable owing to the fact that the organisms involved are deep-seated It has been found, however, that MONSOL LIQUID GERMICIDE, with its bland, but deeply penetrative action, is more effective than any other treatment, and either at full strength or at a dilution of 1-5 will clear up these conditions when all other treatment fails

LIQUID GERMICIDE

A SIMPLE ANALGESIC

The popular belief in the value of external applications for the easing of pain and the lessening of congestion is as well founded as it is universal. There are few illnesses in which, at some stage or other, THERMOGENE brand of Medicated Wadding fails to give relief and comfort. It acts as a mild yet potent stimulant of the local circulation, reducing congestion due to toxic irritation by bringing about a freer flow of blood through the vessels adjacent to the congested area. It is simple to apply, clean in removal, easy of graduation, and harmless yet effective.

THERMOGENE brand of Medicated Wadding is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin stimulating vegetable essences.

THERMOGENE

Brand of MEDICATED WADDING

FREE SAMPLE *A full-size box with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with THERMOGENE brand of Medicated Wadding and its many uses in practice. The Thermogene Co., Ltd., Queen's Road, Hayward's Heath, Sussex*

BI 20

Clinical Report on

LEO GASTROSIC

(FRESH DESICCATED HOG'S STOMACH)

8th May 1931

On April the 7th a woman was admitted to this Hospital with primary (pernicious) anaemia. She was desperately ill and was given two tubes of liver extract daily until April 18th, when 10 grammes of 'Gastrosic Leo' was substituted for it and given daily in stout.

THE PATIENT MADE A REMARKABLE RECOVERY AS THE RESULT OF THE BLOOD EXAMINATION SHOWS

On the third day she was given a blood-transfusion of 300 c.cm.

Date	Red cells	Haemoglobin	Colour index.	White cells
8/4/31	788 000	16%	1·14	7 600
22/4/31	1 376 000	27%	0·8	11 600
2/5/31	4 268 000	55%	0·65	

The outstanding feature of the above report is that the increase in red blood and haemoglobin took place during 11 days with only 10 grammes of "Gastrosic Leo" administered daily, and as the price of "Gastrosic Leo" is only 10s. for 18 packets of 10 grammes each, the improvement in the patient's condition from the 22nd April to the 2nd May only cost 6s. 2d.

IMPORTANT

Although Leo Gastrosic is one third of the price of other makes of hog's stomach extracts the above report conclusively proves that this preparation is equal to them in effect

SECONDARY INFECTIONS — DIMINISHED

The affinity of Kaylene-ol for bacterial toxins renders it particularly valuable in the abdominal type of influenza.

Kaylene-ol detoxicates the saliva and discharges inevitably swallowed when the local lesion is in the nose or throat.

The patient is protected from intestinal poisons generated in food residues which have been imperfectly digested or retained too long by the debilitated gut.

BRITISH PRODUCT MADE AND SOLD BY A BRITISH COMPANY

INSULIN 'A.B.'

The world wide supremacy of Insulin A B' is due to its unequivocal purity no less than to its well known potency and stability under all conditions

Insulin 'A B' contains the minute quantity of phenolic preservative originally recommended by the Medical Research Council and still considered necessary by bacteriologists (*Lancet* Sept 12, 1931, pp 582 584) as a complete safeguard against the development of bacteria that may be accidentally introduced during self-administration

Supplied in three strengths

20 units per c c Packed in bottles containing
5 c c (100 units or 10 doses) 2/- each
10 c c (200 " 20 ") 4/-
25 c c (500 " 50 ") 10/-

40 units per c c Packed in bottles containing
5 c c (200 units or 20 doses) 4/- each

80 units per c c Packed in bottles containing
5 c c (400 units) 8 - each

Full particulars and the latest literature will be sent free to members of the Medical Profession

INJECTION TREATMENT OF

VARICOSE VEINS

The injection treatment of Varicose Veins with a solution of Quinine and Urethane, introduced by Genevrier, gives excellent results It is safe (no fatality after thousands of injections, has been recorded), it is non toxic, non caustic, and produces no general reaction or febrile disturbances

VARIXOL

This is the scientifically prepared solution made at Evans' Biological Institute It contains 4 grammes Quinine Hydrochloride and 2 grammes of Urethane in a 30 c c bottle and is an unusually stable and efficacious preparation It is issued in 30 c c rubber-capped bottles and in ampoules of 1 c c and 2 c c

SODIUM MORRHUATE

Sodium Morrhuate Solution is also used for the injection treatment of Varicose Veins The effect is prompt and striking, it is harmless to the subcutaneous tissues, and very little discomfort arises from its injection

EVANS' Sodium Morrhuate Solution 5%

is issued in rubber-capped bottles of 5 c c, 10 c c, and 30 c c ampoules of 0 5 c c, 1 c c, and 2 c c

Starch in Infant Feeding

Microphotograph of iodine stained faeces of infant fed on starchy food

Microphotograph of normal faeces of breast fed infant

Starch is never found occurring in any type of milk the infant's digestive tract is not equipped for the absorption of starch during the first seven months The addition of starch to the diet of such children makes unjustifiable demands on its alimentary canal, and by disturbing the normal ratio of proteins carbohydrates, fats and vitamins prepares the ground for rickets and scurvy Formerly such addition was recommended on the ground that casein was thereby rendered more digestible The Improved Roller Process employed in the manufacture of COW & GATE Milk Food modifies the casein and renders it so digestible that the curd is as fine and flocculent as that of breast milk Moreover the old fashioned method of adding starchy products to raw milk carries all the risks inherent in the use of raw milk with the ever present danger of tuberculosis and all the other infections carried by raw milk On the other hand COW & GATE is 200 times cleaner than Certified milk, is unvarying in composition and is the safest and most suitable substitute for natural feeding from birth to seven months As an introduction to mixed feeding at the seventh month PEPTALAC the Cow & Gate Predigested Milk Wheat Food is strongly recommended 25% of its starch content is predigested and it has the overwhelming advantage over all other starch preparations employed in infant feeding usually very low in fats of a normal fat percentage It is simply prepared by the addition of water

Cow & Gate Milk Food

Clinical samples of Cow & Gate and Peptalac will be gladly sent on request to any member of the Medical and Nursing Profession

"ALL-BRITISH" PRODUCT

*

STANDARDIZATION OF ONE OF THE INGREDIENTS OF THIS FAMOUS BRITISH PRODUCT

A general survey of milk testing done in the laboratory at Slough Every batch of milk is tested before it leaves the producer, and then re-tested by the Horlick's experts Three of these tests as shown here are carried out not once but 3 or 4 times after arrival

*

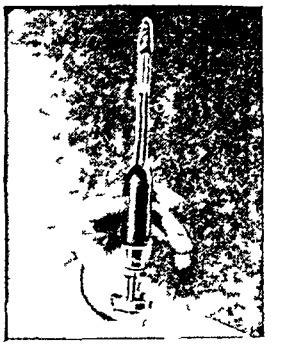
HORLICK'S was originated half a century ago by an Englishman, Sir James Horlick, Bart, and year by year it has won ever-increasing popularity until today it is confidently recommended by the medical profession all over the world

Just now, when patriotic men and women are uniting their efforts to support home industries, it is particularly satisfactory for doctors and nurses to know that Horlick's Malted Milk is an all-British product

ENGLISH DAIRY FARMS SUPPLY THE FRESH FULL-CREAM MILK THAT GOES INTO HORLICK'S

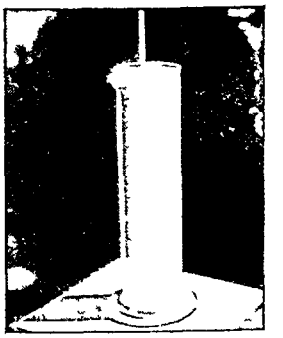
Cows fed on the richest pasture lands of England produce the fresh full-cream milk from which Horlick's is made Barley from the eastern counties—malted at Horlick's own Maltings in Norfolk, and home-milled British wheat only are used in its manufacture

BRITISH EMPLOYEES



Horlick's Malted Milk Company Ltd, is wholly English in directorate and capital From factory hand to skilled technician in the laboratories and test rooms — *right through the organization British labour is employed*

EVEN THE BOTTLES ARE BRITISH!



Only British made material is used in Horlick's factory, even the bottles in which Horlick's is packed and the paper in which it is wrapped are *made in England*

*

HORLICK'S MALTED MILK CO LTD, SLOUGH, BUCKS

Determining the amount of fat present The fat content of milk used in Horlick's is well above Government standards

A lactometer floating in a sample of milk It registers the specific gravity from which can be calculated the amount of solids present

Testing for acidity A measured quantity of milk is put into a glass vessel and neutralized with a standard chemical solution This indicates the freshness of the milk and its suitability for use

A New Efficient and Palatable Preparation of Senna

"LIXEN"
BRAND

Elixir of Senna Pods

An extract of senna prepared by a special cold process
Non-griping Agreeably Flavoured
An advance on the various syrup preparations

1 teaspoonful is equivalent to 12 large senna pods

In bottles of 4 oz and 8 oz for prescribing
40 oz and 80 oz for dispensing

"Lixen" Laxative Lozenges
BRAND

Contain 'Lixen' in a fruit basis
Really pleasant to take
Free from all other purgatives
Appeal particularly to children

Each lozenge is equivalent to 6 large senna pods

In boxes of 12 and 24 lozenges for prescribing
and 100 lozenges for dispensing

Remarks
ON THE
TREATMENT OF TETANUS, DIPHTHERIA, AND OTHER NEUROTROPIC DISEASES BY THE METHOD OF PHYLAXIS
BY

RENE CRUCHET M D
PROFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF BORDEAUX

The interesting and suggestive work published by Dufour a few years ago on the value of chloroform anaesthesia in the treatment of tetanus has not perhaps attracted the attention it deserves This has probably been due to its apparent lack of general application although as will be seen below such is not really the case Dufour[1] in 1925 showed that if anti tetanic serum is administered under chloroform anaesthesia to a case of tetanus unusually good results are obtained This technique was originally adopted by Dufour in order to facilitate intrathecal injections a procedure otherwise difficult of application in contracture and especially if opisthotonos is present

THE VALUE OF SEDATIVES IN THE TREATMENT OF TETANUS

The suggestion of treating tetanus by inhalations of chloroform is not actually original, as Eschallier house physician to Velpeau employed this method as far back as 1847 Chloral later came to be used for the same purpose and was given by mouth subcutaneously or intravenously

Ore who first suggested the intravenous administration of chloral—a method which attracted much attention—did not favour giving the drug by mouth not only because its action then became uncertain but also because of the large doses necessary to produce an effect and of the difficulty if not the impossibility of such large amounts being absorbed He at first greatly preferred the subcutaneous route but in 1872 as the result of his early experiments abandoned this method In 1875 he returned to the subject and came to the following conclusions

> Chloral may be given subcutaneously in one of two ways —either in a weak or in a concentrated solution If the weak solution is used it is ineffective and therefore useless while a concentrated solution produces abscesses and sloughs at the point of injection with unpleasant and even dangerous consequences These facts have been amply confirmed both by animal experiment and in the treatment of patients suffering from tetanus

RESULTS OF INTRAVENOUS CHLORAL

Ore therefore unhesitatingly recommended the direct injection of chloral into the veins This new treatment was first used in November 1872 and in February 1873 on two patients suffering from tetanus The first patient was given nine intravenous injections within the course of three days receiving in all 28 grams of chloral hydrate He died nine days later but as he was moribund at the time of the first injection therapeutic results could hardly be expected The second patient was given a daily intravenous injection of 10 grams of chloral dissolved in 10 c cm of water for three consecutive days He gradually began to improve and within seventeen days (that is twenty four days from the onset of the disease) his convalescence was assured

Ore was of the opinion that the *continuous* anaesthesia produced by chloral allowed time for the *elimination* of the morbid element of the disease In this way the disease became less virulent and passed into the more chronic and therefore more curable stage

In spite of these striking results and of many others obtained in the domain of general surgery intravenous chloral anaesthesia was soon given up So far as tetanus was concerned a cure was rarely obtained Thus in Ore's book[2] published in 1877 out of eleven cases reported only two survived Moreover the intravenous injection of chloral demanded a certain dexterity as any effusion of the drug into the cellular tissue outside the vein was certain to give rise to an abscess Even practised surgeons such as Cruveilhier Tillaux and Lanelongue (of Bordeaux) recorded cases of coagulation of the blood and of thrombosis and phlebitis following the use of this method

RESULTS OF SUBCUTANEOUS CHLORAL

For some time in spite of Ore's view the subcutaneous route was preferred but although successes were reported by Laun (1874) Salter Ribelle Bouchardat Purefoy and others the method was soon abandoned The use of concentrated solutions of chloral was almost invariably followed by abscess and sloughs or by deep cellulitis In 1900 I first suggested that isotonic solutions would possibly avoid these complications and recommended the use of 5 grams of chloral dissolved in 250 c cm of distilled water When first used in a case of tetanus the method worked perfectly and no local complications were observed Injections of anti tetanic serum were given at the same time but the doses employed were small (10 to 30 c cm daily) and were given subcutaneously The results obtained in this case[3] were comparable with those recorded by Ore The attacks of contracture rapidly ceased the patient slept quietly and remained asleep for forty eight hours He then however had a further convulsive attack and died within a few minutes asphyxiated before another injection of chloral could be given

I have on several occasions since had recourse to subcutaneous injections of isotonic chloral for the treatment of tetanus but obtained my most interesting results in 1915 during the war While with the 5/68 Ambulance Service of a great number of wounded I had occasion to treat eight cases of tetanus—three at Tusey near Vaucouleurs and five at Toul three of these patients recovered Acting on the advice of G Canuyt, who was pharmacist to the ambulance and who unfortunately died later in the Flying Corps I used a 1 per cent solution of chloral which though a little more concentrated than the isotonic solution caused no unpleasant local symptoms whatsoever Two to three injections were given daily making a total of 5 grams of chloral in the twenty four hours As the condition improved the dose was diminished until the patient was taking 4 3 2 and 1 gram or less daily In the case of R G which ended in complete recovery chloral was given for the whole period between April 15th and May 14th 1915 In the case of P. who also recovered chloral was given from March 13th to March 30th 1915 beginning with a daily dose of 5 grams and ending with a dose of 0 5 gram I often combined the treatment with a little morphine (1/5 to 1/4 grain in the twenty four hours) and with subcutaneous injections of anti tetanic serum in doses of 10 to 30 c cm daily Occasionally the serum was given intravenously but never in larger doses than 10 c cm Although the treatment failed in five of our cases complete muscular relaxation was obtained life was definitely prolonged some four to eight days and death at least was rendered peaceful and free from the agony of body and mind that otherwise is almost invariably present Moreover these patients were already gravely ill with septicaemia (two had had amputations performed under very bad conditions) before developing tetanus

INTRODUCTION OF CHLOROFORM INTO TREATMENT

We now know that the doses of anti tetanic serum used were too small Much larger doses are now given (Etienne and Benech have injected as much as two to three litres) We have also since learned, in cases of necessity to employ the subarachnoid route with the result that the mortality rate of tetanus has definitely diminished

Certain patients were nevertheless found to be refractory to this intensive treatment and solely with a view to facilitating intraspinal injection of serum certain observers again had recourse to chloroform anaesthesia Remarkable results were sometimes obtained which were assumed to be due to the anti tetanic serum until Dufour raised the question as to whether the chloroform itself might not have some beneficial action in tetanus On investigation this seemed indeed to be the case but for some time nothing further was done These facts however demand an explanation and it is with this aspect of the problem that I now propose to deal

PHYLACTIC ACTION OF CHLOROFORM

Billard the late professor of physiology at Clermont Ferrand was the first to give an original and convincing explanation of the value of chloroform anaesthesia in tetanus Certain other workers had already attacked the problem but none had envisaged it so completely or had seen in it an expression of a universal law It was Billard who first established this conception and who after innumerable experiments first described the phenomenon of phylaxis

With regard to this matter, Billard[5] wrote as follows

> Profoundly convinced of the essential importance of lipoids in the production of phylactic phenomena I wondered whether anaesthetics generally which had already been shown by Nicloux to have an affinity for the central nervous system and in particular whether chloroform which had enabled Overton to establish the existence of lipoids did not have the power of so modifying lipoid equilibrium *in vivo* as to render animals either more sensitive or more refractory to neurotoxins

EXPERIMENTAL EVIDENCE

Experiments with guinea pigs in this direction gave the following results (1) The injection into a guinea-pig of a lethal dose of tetanus toxin produced no reaction if the animal had been anaesthetized for about three minutes twelve to fifteen minutes before the injection An anaesthetized guinea pig is therefore refractory to tetanus toxin (Billard) (2) If the lethal dose of toxin is given some ten to fifteen minutes before the chloroform anaesthesia the animal dies more rapidly than by the injection alone Therefore chloroform anaesthesia administered subsequently to the toxin increases the virulence of the toxin (3) If in the second example, an injection of anti tetanic serum is given either just before or just after the chloroform anaesthesia the amount of serum used being 0 5 c cm per 100 grams of weight, the animal survives It follows therefore that anti tetanic serum administered just before or during chloroform anaesthesia has the effect as in the first case of nullifying the action of tetanus toxin

The above experiments relate to tetanus but Billard's work suggests that similar conclusions might be drawn with regard to other toxins which have a special affinity for the nervous system and particularly to diphtheria Under similar experimental conditions identical results were obtained in cases of poisoning by sparteine and by the venene of the viper here chloroform anaesthesia gave the same successful results as with tetanus toxin

THEORETICAL CONSIDERATIONS

Billard was of the opinion that the beneficial action of chloroform was an example of what he called "phylaxis The preliminary anaesthesia by chloroform impregnated the lipoids of the nervous system in such a way as to render it impossible for the toxins mentioned above to become fixed In other words chloroform acted as a protective or phylactic agent (φιλασσις, protection) This phylactic property has not the same force when neurotropic toxins are already fixed in the nerve centres Chloroform because of its affinity for lipoids does indeed displace toxins already fixed to the lipoids of the nerve cells and exercises therefore, its phylactic action but as the body is by this time considerably weakened it cannot alone manufacture the antibodies necessary for its defence The nervous system by fixing these toxins in its own substance serves to limit and neutralize their action When, because of the greater affinity of chloroform for lipoids these toxins are set free it is in a body incapable of further resistance The problem becomes quite different however if an antitoxin in the form of a serum is supplied at the same time The toxins in circulation are at once neutralized and the infection is cured

In conclusion, it would seem that when a patient is gravely ill from some neurotoxin such as tetanus or diphtheria, the best method of phylaxis is to inject large doses of antitoxin under chloroform anaesthesia

TECHNIQUE AND RESULTS

Tetanus.—As we have seen above the earliest cases reported were those of Dufour and his pupils who applied the method in the treatment of tetanus Similar cases have since been published by Rivina Archambault and Friedman Feissier and Coste Bernard (of Lille) Pagniez, Guillain and de Sèze by Brulé and Lenegre Maurice Villaret and Haguenau

We have personally treated five cases of tetanus in children by the phylactic method of chloroform anaesthesia in our wards at the Clinique Médicale des Enfants Three of the children recovered I have also treated two other cases in men with complete success In two cases in children the contractures gradually disappeared, the patient lost his pain and trismus and became quiet and drowsy life was prolonged but death finally ensued In other words the disease ran the same course as it has been observed to do when chloral is given in large doses

Nevertheless we are convinced that this method will give still better results if it is practised according to the following rules although we must admit we have not always followed them ourselves (1) The injections of anti-tetanic serum should be given either immediately before or during chloroform anaesthesia When utilizing the intraspinal route subcutaneous injections of 50 80, or 100 c cm should also be given from the start In fulminating cases the serum should be given intramuscularly or even intravenously The treatment should end with a subarachnoid injection of 10 to 30 c cm according to the severity of the case It is sometimes necessary to repeat the treatment a second time within the twenty four hours but as a rule it need only be given once daily (2) The mistake that is most frequently made is to postpone the phylactic treatment too long to give it in the last and final resort It should on the contrary, be commenced at the onset of the disease, before the nervous system is too much involved and when the body has some power of resistance still left

Diphtheria.—The nervous sequelae of diphtheria which have long been described have of late years become increasingly and unusually severe Hitherto the phylactic

method of chloroform anaesthesia has not been applied to diphtheria in spite of the suggestive experiments of Billard in this connexion. Since February 1930 we have tried the method in six cases, four without any success. We must frankly admit however that the treatment was applied only when the patients were *in extremis* so that no really satisfactory conclusions can be drawn from these cases.

It is absolutely necessary to intervene early if the method is to be applied at all. As soon as nervous complications begin to appear chloroform anaesthesia should be at once combined with the administration of large doses of anti-diphtheritic serum following the same technique as for tetanus and giving the serum subcutaneously intramuscularly or even in the hypertonic cases intravenously. The intraspinal route might also be employed although this to our knowledge has not yet been tried in diphtheria. Such are the general indications which we advise and which we shall ourselves follow in the future.

Encephalomyelitis and Poliomyelitis.—The phylactic method of chloroform anaesthesia might by analogy be used in encephalitis and poliomyelitis but it would be necessary to have at our disposal corresponding specific serums. As far as poliomyelitis is concerned Petit's anti-poliomyelitis serum might well be employed in this way and may possibly give far better results than those obtained hitherto.

Against encephalomyelitis there is as yet no specific serum but it is interesting to note that urotropine which was quickly found to have a favourable therapeutic effect in this condition probably acts in the same phylactic way as chloroform. Urotropine becomes decomposed in the tissues and gives rise to formaldehyde which displaces the toxins from the nerve centres and becomes fixed to the lipoids of the cells. Billard's experiments with urotropine suggest this conclusion. As with chloroform similar results were obtained if urotropine is injected into a guinea pig some fifteen minutes after the administration of a toxin (tetanus anatoxin) the animal dies more rapidly. But toxins differ among themselves and it is possible that if the toxins of encephalitis were liberated in the blood stream the body would be better able to deal with them than when they are fixed in the central nervous system.

Other Indications.—Although so far we have only discussed the more common neurotropic diseases it is evident that the phylactic method might quite well be applied to other infections having a particular affinity for the nervous system. Among these are certain cases of influenza typhoid fever herpes zoster varicella[6] typhus sleeping sickness and of poisoning by strychnine phalline snake bite the botulinus bacillus curare etc.

Conclusions

For purposes of simplification we have confined our attention to the use of *chloroform alone* as a phylactic agent though as we have seen urotropine may act in the same way. We must add however that Billard in experiments of the highest ingenuity has shown that sparteine sulphate gardenal and especially certain mineral waters possess the power of similarly protecting the nerve centres. Further research may discover yet other phylactic substances. Although Billard considered his discovery of phylaxis to be of theoretical interest only it has nevertheless been shown by later workers to have practical implications of the highest order and to offer therapeutic possibilities of the greatest value.

This short memoir which Professor Achard read for the first time at the Academie de Medecine of Paris is written solely with a view to giving an indication of the results that can be achieved by phylaxis of showing that we have now in our hands a method of wide application capable in the future of leading to considerable advances in the treatment of the neurotropic diseases.

DIAGNOSIS OF DRUNKENNESS FROM THE EXCRETION OF ALCOHOL

BY

SYDNEY SMITH, M.D.

REGIUS PROFESSOR OF FORENSIC MEDICINE

AND

C. P. STEWART, M.Sc., PH.D.

CARNEGIE TEACHING FELLOW

(From the Departments of Forensic Medicine and Medical Chemistry, University of Edinburgh)

As part of a more extensive study we have carried out a number of experiments on the excretion of alcohol by human subjects. In all these experiments the excretion both by the lungs and by the kidneys was measured and the condition of the subjects with respect to intoxication was observed by various psychological tests and by the routine methods of examination used by police surgeons. It seemed to us desirable in view of the fact that estimation of alcohol in the breath[1] and urine has been recommended as a test of drunkenness that our experiments should be separately reported especially as they do not support the use of this method of diagnosis.

The subjects of our experiments were all young healthy men and were all light or moderate drinkers. The experiments all commenced at about the same time three hours after a light lunch. Except in one or two cases when gin was used the alcohol was given in the form of whisky the same brand being used throughout and was diluted with an equal volume of soda water. Drinking water or soda water was allowed during the experiment. Samples of air and urine were collected before the alcohol was ingested and periodically afterwards. Psychological and routine tests were made at regular intervals the examination in a number of experiments being carried out by a police surgeon Dr. Cameron to whom our thanks are due.

For the estimation of alcohol in the expired air the subjects blew air through a solution of potassium bichromate and sulphuric acid the delivery tube being terminated by a disk of Jena sinter glass in order to ensure the formation of small bubbles and consequently the complete absorption of alcohol. The air then passed through a flow meter placed with a dial facing the subject who was instructed to stop when the required volume of air—usually five litres—had passed through. Control experiments with air saturated with alcohol vapour showed that at the rate of blowing adopted the alcohol was completely absorbed. The amount of alcohol absorbed and oxidized by the bichromate was determined as usual by the addition of potassium iodide in excess and titration with sodium thiosulphate. The quantities and concentrations of the solutions used were those recommended by Southgate[2] for the estimation of alcohol in urine. The analysis of the urine was carried out by the method and with the apparatus described by Southgate.

In the air analysis a fallacy may be introduced by the difficulty of obtaining strictly comparable samples If the expiration is complete the air analysed will include a larger amount of alveolar air with a relatively high alcohol content than if the breathing is shallow Control of the breathing throughout the experiments is difficult but most of our subjects have produced the complete sample of five litres in five or six breaths As intoxication increases, however deep breathing appears to become difficult, at any rate, there is a strong tendency to shallow breathing The danger is illustrated in Fig 1 In that experiment the subject on each occasion of air sampling attempted to produce the five litres required in as few breaths as possible and gradually reduced the number from ten to three As a result the later samples contained more alveolar air than did the earlier ones and the entirely fallacious curve shown in the figure was obtained

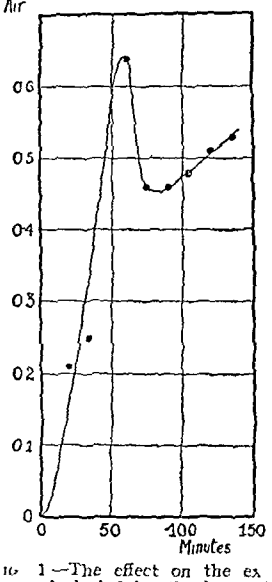

Fig 1—The effect on the excretion of alcohol by the lung of altering the depth of breathing

RELATION BETWEEN THE ALCOHOL CONCENTRATION OF THE BREATH AND THAT OF THE URINE

According to Bogen[3] analysis of the expired air offers a convenient means of ascertaining the alcoholic concentration of the blood since the quantity of alcohol in the expired air bears a definite relationship to that in the urine and therefore to the amount in the blood Our results entirely fail to confirm this statement The curve showing the course of excretion through the lung is of the same general shape as that for kidney excretion (Fig 2) but the maximum concentration in the breath is usually reached much earlier than it is in the urine In Fig 2 we have plotted a series of curves showing the alcohol concentration in the breath of a number of individuals after ingestion of 216 c cm of whisky and Fig 4 shows the alcohol concentration in the urine in the same and other experiments Examination of these curves shows that there is no constant ratio between the concentration of alcohol in the breath and in the urine Thus forty minutes after the ingestion of the alcohol C_1 is excreting three times as much by the lung as is G (not charted) but only twice as much by the kidney after ninety minutes the relative amounts in the breath remain approximately the same while in the urine G is excreting slightly more than C_1

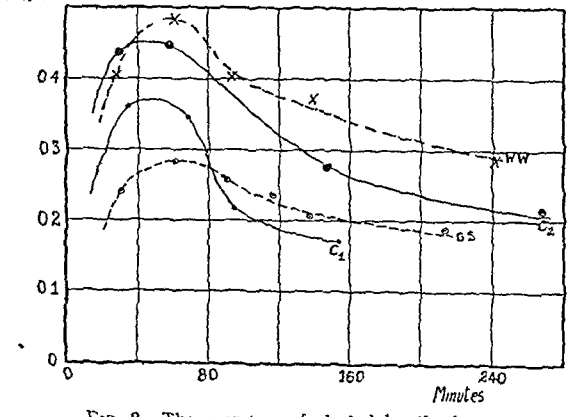

Fig 2—The excretion of alcohol by the lung

In the experiment with W W the ratio between the concentration of alcohol in the breath (per litre) and that in the urine (per c cm) is 0 34 0 31, 0 31 and 0 41 in the different pairs of samples in that with G S the ratio is 3 4 0 36, 0 25, 0 27, and 0 32 and in that with C it is 2 25 0 65, 0 34 and 0 26 Even if the first ratio in each series be excluded these figures show too great a variation to justify the claim of a quantitative relationship between the concentrations of alcohol in the breath and urine

EXCRETION OF ALCOHOL BY THE KIDNEY

It has repeatedly been stated that there exists a definite relationship between the alcohol concentration of the blood and that of the urine Thus Southgate and Carter give the ratio as 1 to 1 35, and other workers have obtained similar though not identical figures It seems to us however that in calculating these ratios, insufficient attention has been paid to the fact that whereas a sample of blood shows the concentration of alcohol in the blood at the moment of withdrawal of the sample a sample of urine shows merely the average concentration of alcohol in the kidney secretion during a period of time Hence it appears that the exact ratio found experimentally will depend on the frequency with which urine samples are collected and compared with the blood Thus if, as seems possible * the true ratio is unity and the concentration of alcohol in the blood at a given moment is equal to the concentration in the urine secreted at that moment it is to be expected samples of both fluids being collected at the same time that

1 If urine is collected at the end of a period during which alcohol is being absorbed and the blood concentration is increasing the concentration of alcohol in the urine will be less than that in the blood

2 If the time during which the urine sample has been secreted covers the peak of alcohol absorption the concentration of alcohol in the two fluids will be approximately equal

3 If the urine sample covers a period during which the concentration of alcohol in the blood has been falling the concentration of alcohol in the urine will be greater than that in the blood The shorter the periods during which urine is allowed to collect in the bladder the closer will be the approximation of the curves of blood and urine alcohol concentration

A second result which is to some extent dependent on the same factor—the time interval between the successive samples of urine—is the shape of the urine alcohol concentration curve This is true in fact not only of urine, but also of blood The longer the interval between samples, the smoother will be the curve a fact which is illustrated in Fig 3 Here the curve with black dots is obtained by plotting the results of half hourly samples of urine The curve with circles is obtained from the same experiment by combining pairs of analyses to give the concentration of alcohol in hourly samples If the rate of excretion of alcohol by the kidney is a true reflection of the concentration of alcohol in the blood, a curve of the black dotted type is more probable than one of the shape found by Mellanby[4] and by Southgate and Carter[2] The curves given by these authors indicate a constant rate of disappearance of alcohol from the blood and therefore since the actual

* This supposition which implies a simple filtration of alcohol through the kidney is supported by the fact that while the *concentration* of alcohol in the urine follows a regular curve the *amount* does not In other words the concentration does not depend on the volume of urine passed Experiments of our own on animals indicate that with urine collected over very short periods the ratio between blood and urine alcohol concentrations is approximately unity

amount excreted by the kidney is negligible a constant rate of oxidation of alcohol no matter what the concentration in the blood Now this is contrary to experience with other types of foodstuff and even in the case of alcohol it is not supported by any evidence save the shape

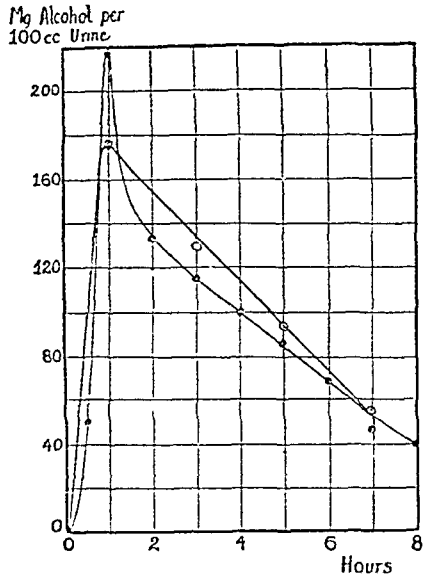

FIG 3—The influence of the interval between successive samples of urine on the shape of the kidney excretion curve

of the urine excretion and blood concentration curves as found by Mellanby The metabolism experiments carried out by him show that alcohol can be metabolized at the average rate of 10 c cm per hour not that it is metabolized at that rate in all circumstances The excretion curves we have obtained from samples of urine collected at short intervals fit in with this view for though they indicate that the rate of oxidation of alcohol is to some extent dependent on the concentration in the blood they show that the time required for the complete removal of alcohol from the body is roughly proportional to the amount ingested

MEDICO LEGAL VALUE OF DETERMINATIONS OF ALCOHOL IN THE URINE AND BREATH

Except as showing that the suspected person has or has not consumed alcohol within a short time of the test estimation of alcohol in the breath appears to be valueless Since as we have shown there exists no constant relationship between the amount of alcohol in the breath and that in the urine (or therefore that in the blood) it is not possible to draw from analyses of the breath valid conclusions as to the amount of alcohol consumed As to the diagnosis of drunkenness the arguments set out below apply to expired air as well as to urine

So far as the urine is concerned determination of the alcohol content can be of value in the diagnosis of drunkenness if

1 The concentration of alcohol in the urine bears a constant relationship to the concentration in the blood
2 The concentration in the blood bears a constant relationship to the concentration in the tissues
3 The concentration in the blood and tissues is an index of the degree of intoxication

Leaving aside for the moment the question of the degree of intoxication it does seem that the first two factors are satisfied sufficiently closely to allow of urine analysis giving an idea of the minimum amount of alcohol consumed For it appears that at the moment of secretion urine contains about the same concentration of alcohol as the blood, though in actual practice the relation departs somewhat from this simple one since the urine actually obtained is secreted over a period of time during which the concentration of alcohol in the blood is changing There is also evidence that the tissues at any given moment contain approximately the same concentration of alcohol as the blood the term tissues being taken as including all the large organs and the skeletal muscle but not the bones and fat deposits which are almost alcohol free Thus from the blood concentration—and less exactly from the urine concentration of alcohol—it is possible to calculate the approximate total amount of alcohol in the body at any given time and therefore the minimum amount consumed In this calculation allowance must be made for the weight of the skeleton and adipose tissue which together normally account for about a third of the total body weight Hence the minimum amount of alcohol taken is equal to (about) 2/3 × body weight × percentage of alcohol in blood Closer approximation can be made if one knows the time that has elapsed since the ingestion of alcohol since that allowance can be made for the amount metabolized The crudity of the calculation however renders such refinements dangerous

The amount of alcohol calculated from the blood concentration is strictly a minimum but inspection of certain of our experimental results shows the danger of attempting to go further and to calculate the actual amount consumed The variation in the rate of excretion in the time between ingestion and maximal blood concentration and the possible variation in the rate of metabolism not only among different individuals but in the same individual on different occasions all tend to make such extrapolations unsafe A study of our curves shows very

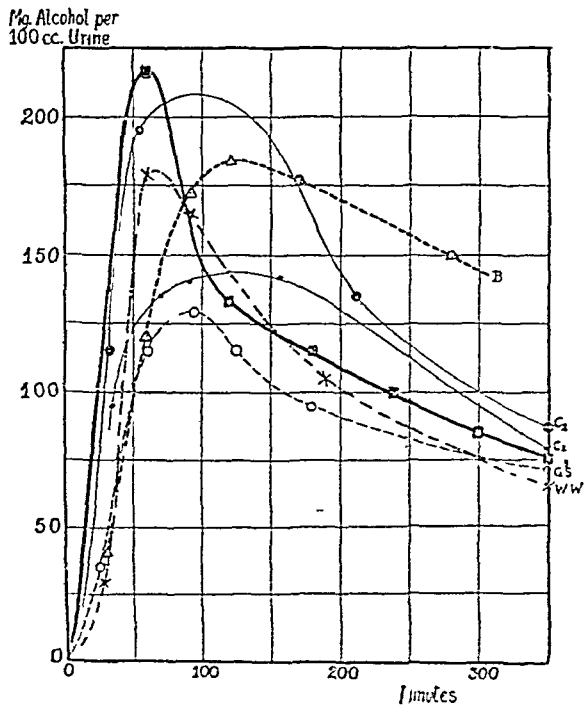

FIG 4—The excretion of alcohol by the kidney in different individuals who have taken the same dose

clearly that this danger is not imaginary and that the differences in the alcohol concentration of the urine found in different experiments with the same consumption of alcohol in similar circumstances cannot be correlated either with body weights or with the habits of the subjects in regard to the drinking of alcoholic liquors Thus in Fig 4 G S who is practically teetotal and weighs 12 st,

a matter of common experience that the occurrence of inflammatory ear complications in any given exanthematous case is far more likely in childhood than in adult life

The reason for this is not clear but is usually alleged to be due to the presence of adenoids in the child and the cleaner nose and nasopharynx in the adult Although this explanation may hold good for exanthematous cases, it is noteworthy that persons who have frank intranasal suppuration such as ethmoiditis and atrophic rhinitis are not apparently more prone to acute otitis media, during influenzal epidemics than those with clean noses Some modern immunological investigations suggest that some localized tissue immunity is conferred by the presence of chronic sepsis and if this is so it may explain why these cases resist the acute infection

Nasal obstruction appears to be a factor in favouring the incidence of otitis media though I am of opinion that persons who have a little or only partial structural obstruction are more prone to acute ear trouble than those who are marked mouth breathers at all times and have practically no physiological nasal function

Nose breathers are quickly obstructed to some degree by the swelling of the turbinates and mucous membrane consequent on the acute catarrhal infection of the airway and efforts to breathe through the nose or to clear it for this purpose are a potent mechanical factor in carrying infection to the middle ear I believe that a patient whose nose becomes quickly occluded by an infection of the upper airway would be wise to avoid all efforts at attempting to clear it and accept the role of mouth breather for the time being until the turgescence gives way just as patients should do for the first two or three days following a nasal operation There is however a popular belief that mouth breathing is a stigma and persons holding this view strongly will continue to make violent efforts to clear the air passages

The greatest danger to the ear arises not during the turgescent stage of acute rhinitis in influenza, but in the subacute stage when the stuffy swollen feeling has given way to a serous secretion and the latter is passing into a muco purulent form of discharge The patient begins then to find the airway clearing and delights in blowing his nose vigorously to establish breathing and nasal comfort but is unfortunately inflating his middle ears and may finally succeed in forcing some septic material into a tympanic cavity not yet infected This seems to be the correct mechanical interpretation of what so frequently happens in these cases and the natural corollary as to the line of treatment would appear to be obvious—namely to avoid blowing the nose with both nostrils occluded The use of the handkerchief would be wisely limited to wiping away any secretion which escaped from the nostrils and any secretion falling on the soft palate from the posterior nares should be sniffed into the pharynx and expectorated

Local treatment to the nose in any liquid form is contra indicated and is likely to be harmful Vapours such as those of menthol and benzoin co may be soothing and are certainly harmless The skin and bowels should be kept acting freely to eliminate as quickly as possible the toxins which course of the nasal turgescence and infection To general shape as the and almost continuous free action maximum concentration should be carefully covered from much earlier than it is in has disappeared This is a plotted a series of curves showing importance I have tested in the breath of a number of individuals 2·16 c cm of whisky and Fig 4 concentration in the urine in the to treat the ear experiments Examination of these curves myringotomy there is no constant ratio between the concentration of alcohol in the breath and in the urine The trying strengths of from 2 to 10 per cent, and await the subsidence of the inflammation or the rupture of the membrane with suppuration, should no mastoid complications supervene

If the treatment is by early *myringotomy*, this is done on the plea that it relieves pain and tension The old indication for incision of the membrane was a bulging drum head hence the name of paracentesis as applied to the operation but from what I can hear nowadays there is a new school which incises practically every inflamed membrane This is a grievous mistake and will yield the most uncertain and doubtful if not positively harmful results Routine surgery is bad surgery and there is no need for it if we take the trouble to study our physiological guide and ask what Nature is trying to do by means of *vis medicatrix naturae*

All these acute middle ear infections are either streptococcal or pneumococcal, or both and the pyrexial reaction is considerable and only subsides when some degree of immunity has set in which usually takes two or three days

To inflict any type of trauma even surgical upon inflamed tissues during this period of active reaction is to impair the chances of rapid recovery if not to damage them seriously but when the reaction has subsided owing to the establishment of immunity the position becomes entirely changed As a matter of fact when we see a bulging drum head we have practically arrived at the latter stage

If the primary airway infection has caused a sharp pyrexia which has subsided and this is followed by a middle ear inflammation with only a mild reaction an early myringotomy may be done (should indication for its performance such as bulging drum head pain and tension be present) with the expectation of a satisfactory result but if the earlier airway reaction was mild and the middle ear one severe (perhaps in the latter due to a new or more virulent organism) then time must be allowed for the establishment of some immunity as evidenced by the fall in temperature before inflicting even a surgical trauma on the inflamed tissues in short never operate in the hot stage and it may become unnecessary in the cold

DISEASES OF THE HIP-JOINT AND ITS IMMEDIATE NEIGHBOURHOOD *

BY

JAMES F BRAILSFORD M D M R C S

HONORARY RADIOLOGIST THE ROYAL CHILDREN'S HOSPITAL BIRMINGHAM

For the diagnosis of most diseases a careful correlation of the clinical laboratory and radiographic findings must be made but these individual means of diagnosis are not always of the same value There are diseases the diagnosis of which rests almost entirely upon the clinical or the laboratory or the radiographic findings In the diagnosis of hip joint disease the radiographic appearances are of the first importance because a number of different pathological conditions give almost identical signs and symptoms Frequently the radiograph is diagnostic and reveals a pathological condition of much graver significance than the clinical findings suggest In the adult for example radiographs have revealed fractures of the femoral neck in patients who have been treated for weeks or months for sciatica following a trauma so slight that the clinician has apparently not thought of the possibility of fracture Again it is not infrequent for the radiograph to show the typical appearance of Paget's disease or

* Abstract of paper delivered in Belfast to the Ulster Medical Society

secondary carcinoma of the bone in cases which have been regarded as chronic sciatica

An examination of the radiographs of hip joints during the past five years at the Royal Orthopaedic Hospital the Warwickshire Orthopaedic Hospital the Queen's Hospital and the Carnegie Infant Welfare Centres Birmingham has shown the following pathological conditions

In Persons under 20

Congenital dislocation of the hip joint	88	Syphilis	4
Tubercle	60	Tumours	4
Perthes's disease	43	Fracture of femur neck	3
Septic arthritis	27	Dislocation of hip joint	3
Slipped epiphysis of femur	26	Myositis ossificans	3
Infantile coxa vara	15	Osteochondrodystrophy	2
Rachitic coxa vara	15	Cyst in femur neck	2
		Haemophilic changes	1

In Persons over 20

Osteo-arthritis	130	Secondary carcinoma	8
Chronic arthritis	73	Sarcoma	3
Septic arthritis	30	Cyst of femur neck	2
Fracture of femur neck	30	Syphilis	2
Paget's disease	12	Charcot's disease	1
Dislocation of hip joint	10	Hydatid	1

For success in the treatment of most of these conditions particularly those occurring in the child early diagnosis is essential While it can be said that certain cases of tubercle of the hip joint do not show radiographic changes in the very early stages one should not be deterred from having a radiograph taken as this often reveals greater destructive changes than are suggested by clinical examination The radiographic findings prove that the earlier a congenital dislocation is detected and treated the better the final result The condition of infantile coxa vara has been diagnosed from a radiograph in a child of 7 months This condition shows some of the features of Perthes's disease in that the bone of the femoral neck becomes fragmented softened plastic and yielding to pressure As a general rule the active phase passes after a few years normal bone is laid down and a sound femur produced retaining however the deformity caused by pressure on the disorganized structure during the active phase The radiographic appearance of this and Perthes's disease suggests that if the plastic bone were put at rest and freed from pressure little deformity would result Slipping of the femoral epiphysis usually occurs without any marked trauma Injuries which result in separation of epiphyses show on the radiograph that the lesion is not confined to the displacement of the epiphysis but that fragments of the diaphysis are carried with it Injuries near the end of bones not uncommonly result in fractures above the epiphyseal line leaving the latter intact Fracture of the femoral neck in children is relatively rare but when it does occur the epiphysis is not usually displaced When the epiphysis is displaced it is frequently impossible to get any history of trauma and the radiographs do not show detached fragments of the femoral neck The condition being frequently bilateral radiographic appearances suggest that it is due to a shearing strain on a disorganized metaphysis Deformities of the pelvis seen in children who have had rickets show remarkable improvement after orthopaedic treatment marked coxa vara being almost completely restored to the normal Radiographs of the adult show that a large proportion of fractures of the neck of the femur (about 50 per cent) fail to unite and that pronounced bone changes often occur in and around the hip joint after dislocation Early and obvious osteo-arthritic changes are not unusual These factors have a very important bearing in compensation cases

Paget's disease of bone is a much commoner condition than is usually taught Its presence is often revealed by a radiograph of the pelvis years before the bending of the long bones might have caused the clinician to suspect it Simple cysts in the neck of the femur may develop to such a size that fracture results from slight trauma but some of them having reached a certain size cease to develop and ultimately become surrounded by sclerosed bone calcification of the contents occurring Hydatid cysts of the bone may remain undiagnosed for ten or more years and eventually lead to the patient's death The first indication of malignant disease may be seen in the radiographic examination of a patient with persistent sciatica erosion of the bone near the hip joint resulting from secondary deposits

A NOTE ON THE EPIDEMIOLOGY OF TINEA CAPITIS

BY

G H PERCIVAL M B Ch B Ph D F R C P Ed

ASSISTANT PHYSICIAN SKIN DEPARTMENT ROYAL INFIRMARY EDINBURGH

The clinical appearances of microsporon and trichophyton infections of the scalp and the varying distribution of the causative fungi according to geographical localization are common knowledge As less is known regarding the infectivity of the disease and its occurrence in epidemic and endemic form a study of its incidence amongst Edinburgh school children for the past eighteen years may be of interest During this period 2,701 cases of tinea capitis have been treated in this school population

In Edinburgh all children attending education authority schools who are found to be suffering from ringworm of the scalp during routine school medical examination are segregated in a special school This system has been in operation since 1912 Here in addition to teaching local treatment is carried out daily though the children do not reside in the school X ray or thallium treatment is given at the Skin Department of the Royal Infirmary Edinburgh the local treatment being also supervised there As has been reported in a previous paper on the treatment of scalp ringworm with thallium acetate the period of isolation at the special school is about 135 days when epilation has been produced by x rays and 113 days when thallium acetate has been used The parents are told how to carry out local treatment at the week ends and are warned of the risk of infection to other children

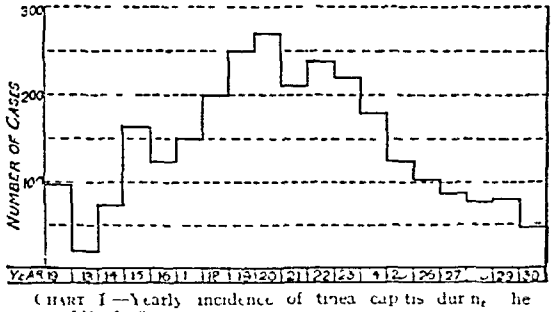

CHART I.—Yearly incidence of tinea capitis during the years 1911–1930

During vacations treatment is entirely in the hands of the parents but is still supervised at fortnightly intervals in the Skin Department of the Royal Infirmary

The medical inspection of schools is conducted throughout each term and is not concentrated on any particular part of a term In addition to cases discovered during routine school medical examination a small number of cases are first seen in the Skin Department and are referred from there to the special school

The curve of yearly incidence of tinea capitis (Chart I) shows that the disease remains endemic in spite of strict medical inspection and supervision of treatment There appears to have been a wave of increased endemicity during

the years 1918–24 This may be more apparent than real The figures from 1912 to 1917 may well undervalue the actual numbers for the system of isolation was during the earlier part of that period an innovation whilst school medical inspection was less rigorous during the war than

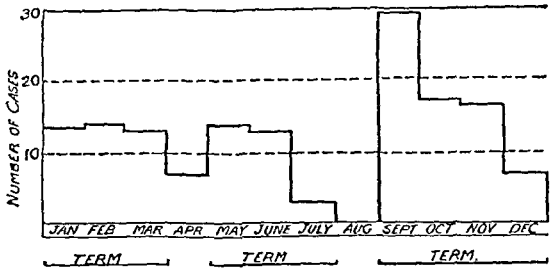

CHART II—Average monthly incidence of tinea capitis during the period 1912–1930

afterwards Owing to the possibility of a naturally occurring periodicity in the case incidence (apart from the effect of isolation and supervision) it cannot be concluded that the decreasing incidence during the years 1925–30 indicates the slow elimination of the disease as a result of

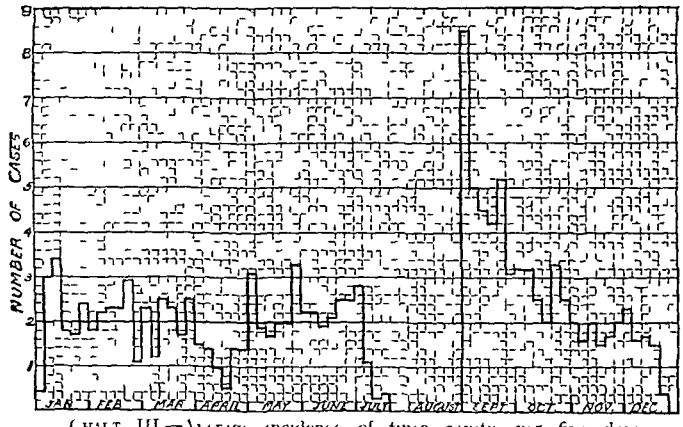

CHART III—Average incidence of tinea capitis per five days during the period 1912–1930 (One small square=five days)

preventive measures The explanation may rest in a lower virulence of the infecting fungi or in a combination of both these factors As far as the available figures show the disease is exactly comparable to scarlatina or diphtheria as regards its occurrence over a period of years

The monthly and five day incidence charts (Charts II and III) show clearly that the isolation of cases as they occur has a beneficial influence on the case incidence or the number of contact infections during the school terms This holds good in spite of the fact that most of the children are highly infectious for at least a few days before they are isolated and when the lesions are developing to recognizable dimensions The highest figures of incidence are reached at the commencement of the school terms—that is following a period during which fresh cases probably escape detection for a longer time than is the case in term time when the children are subjected to routine medical inspection The magnitude of the rise in case incidence after a vacation seems to vary directly with the length of the vacation It is recognized that in a given community of children infection may be acquired from outside sources during a vacation as a result of temporary changes of abode or of temporary changes in the distribution of the general population Infections acquired in such a manner cannot however account for more than a small increase in case incidence in any one school population and the increase noted can only be attributed to the natural spread of the disease in the school locality as a result of the absence of any controlling measures to deal with new cases during the vacation period This fact raises the question whether infection is more readily acquired in home surroundings than at school The curve of incidence can be to a *great extent accounted for by the former hypothesis*

The average number of cases recognized during the first five days of September over a period of eighteen years was 8·5—the highest incidence of the whole year Each of these cases had a greater or less opportunity to infect others before they themselves were recognized and isolated If school contact offers ample opportunity for several children becoming infected from one child when there is a limited period during which infection can occur then an abrupt rise in incidence might be expected during the second third or even fourth five day period of September This however does not occur and there is a steady diminution in case incidence during the remainder of the term It suggests that tinea capitis spreads slowly and that a sudden rise in case incidence does not take place when infection is first introduced into a non infected population The endemicity is due to a slow spread of infection and to the occurrence of infected cases which are overlooked for a considerable period The disease is not characterized by sudden sharp epidemic While variations in the virulence of the infecting *fungus may account for the fall in case incidence* during the past six years it cannot account for the variations in the monthly and five day incidence calculated from figures taken over a period of eighteen years

That cases of tinea capitis already under treatment do not act as potent sources of infection is shown by the decrease in case incidence during school terms This occurs despite the fact that the children are only segregated during school hours

On account of the epidemiological characters of the disease it is doubtful whether any system capable of being put into operation under existing conditions where supervision throughout the entire year is impossible would be able to eliminate the disease completely from a large school population

PUERPERAL SEPSIS AND PROPHYLACTIC VAGINAL ANTISEPSIS

BY

C L SOMERVILLE M D

SURGEON IPSWICH AND IPSWICH MATERNITY HOSPITAL

It has always seemed to me that the ordinary conduct of a simple forceps delivery was a contradiction of all the rules and axioms of surgical procedure It is well recognized that the vagina contains organisms in every case Recent work has shown that in the apparently normal woman staphylococci are present in about 60 per cent, streptococci in 42 per cent and the deadly *S haemolyticus* in 2·7 per cent while other organisms such as *Bacillus coli* are also present In the simple forceps case the operator sterilizes the skin of the patient's perineum his own hands, his gloves and instruments and then straightway passes them through the bacteria laden mucus of the vagina into the uterus—over a surface and through a medium that no general surgeon would tolerate for one moment It is true that the vagina may be scrubbed out with ether soap but this is

impossible when the head occupies most of the pelvic cavity I am safe in saying that most forceps operations are conducted without any treatment of the vagina whatever Yet we expect these cases to remain afebrile!

No amount of ante natal care will obviate the introduction of forceps into the tired exhausted uterus nor an adherent placenta requiring manual removal We know that the bacterial flora of the vagina is rich and yet we go on performing these operations realizing that we are inevitably infecting the uterus

Let me present another aspect what occurs just before 'crowning' of the foetal head takes place? The foetal head has been driven down on to the perineum and is bulging through the vulva in the intervals between the pains it retreats out of sight into the vagina There is a to and fro motion of the foetal head and the foetal body—down into the vagina to be smeared with bacteria-laden mucus back into the uterus to deposit its burden of infection there What occurs just before crowning also occurs in a lesser degree throughout the second stage of labour from the time when the cervix is sufficiently dilated to allow the head to protrude through and the sac of membranes has ruptured It follows therefore that we must entertain a new conception—namely *that every woman has her uterus infected from her own vagina during the normal natural course of delivery*

I am well aware that recent work on cultures from the interior of the uterus after labour shows a great proportion as sterile but I suggest first that no cultural proof is required and secondly that the cultural methods of some of the investigators are not calculated to show up this point

There is no dispute about the existence of the flora of the vagina hence if the sterile foetus is dipped into the vagina it becomes infected If the infected foetus is withdrawn into the sterile uterus the latter is infected It is axiomatic and no further proof is required I believe there is considerable confirmatory evidence of my views in the following facts known to all—namely the increased morbidity in cases of (1) early rupture of the membranes—since this allows the foetus to come into contact with the vaginal walls for a much longer period than when the foetus is enclosed in the intact sac until late on in labour and is so prevented from touching the actual vaginal walls (2) Portions of membrane being retained I do not believe that if the pieces of membrane were really sterile they would be in the least likely to promote sepsis The amount of catgut used in haemostasis and suture of a laparotomy wound must in its original unspun form exceed the size of any portions of membrane usually left behind yet clean laparotomy wounds do not become septic The correct explanation is that the retained membrane is not sterile but is infected as I have shown (3) Cases of so-called dry labour where there is no liquor amnii left to flush out the sac of membranes after the expulsion of the foetus (4) When the placental site is in the lower uterine segment—that is nearer the route of extension upwards from the vagina through the open cervix There is the least likelihood of a morbid temperature when the placenta separates by Schultze's method Here the placenta and sac of membranes are turned completely inside out and no part of the infected foetal surface touches the uterine wall In Duncan's method of separation the membranes are often torn off from a part of the edge of the placenta this allows infected material from the interior of the sac to escape into the uterus

Another unconsidered detail is the movement of the umbilical cord—for example in premature and ineffectual attempts to express the placenta The cord in these cases can be seen to come down a couple of inches and recede again This is not of no importance What surgeon would allow an umbilical cord covered with discharges and vaginal mucus to be dipped into a patient's abdomen? We all know what would happen if it were

Then again during the first stage when the cervix and lower uterine segment are dilating the membranes cannot stretch equally well and the vertical split in the membranes is frequently demonstrable when the after birth is expelled I mention this to show that a portion of the uterine wall is frequently exposed to the rubbing action of the foetus during pains and that organisms are consequently deposited not simply in the sac of membranes but on the uterine wall If we consider these points then those cases of virulent sepsis in normal labours with no vaginal examinations whatever will not seem so inexplicable Why should we in these cases try to find a scapegoat in infected teeth or tonsils or bowels? People with much dirtier teeth and just as infected tonsils and bowels are subjected daily to major operations as also are patients debilitated from long illnesses profoundly shocked blanched from loss of blood all these reproduce varying conditions after labour and yet their clean operation wounds do not become septic Which of us removes an adherent placenta without misgiving? Yet I maintain there is no physical reason why a gloved hand could not be introduced into the uterus without carrying with it any infection except from the patient's own vagina

The natural corollary of these beliefs is that we should make some attempt to sterilize the vagina as soon as possible in labour because when the head occupies the pelvic cavity a great portion of the vagina is out of our reach Even if it were possible to sterilize the vagina we are still confronted with the problem of the cervix A large percentage of women—multiparae especially—have leucorrhoea Most of the discharge in leucorrhoea is from an infected cervix, where the organisms are buried in the deep racemose glands Sometimes when introducing bougies for inducing labour I have grasped the lip of a patulous os with a fenestrated sponge forceps instead of a vulsellum and have remarked the plugs of yellow caseous matter squeezed out of the gland orifices just as caseous secretion can be squeezed out of tonsil crypts in tonsillectomy The difficulties should not deter us however if we believe the principle correct and I hope to show that a very definite decrease in morbidity can be attained I should like to add how illogical it seems for us to take up the attitude that we should not meddle with the vagina during labour when we consider what we do in gynaecological operations such as dilatation and curetting or inductions of labour Every attempt is made in these to sterilize the vagina by swabbing with such antiseptics as iodine and I would cite the success of these operations as measured by freedom from serious after infection It is extraordinary that one and the same man will take precautions for a dilatation and curetting or an induction and will deprecate them for a forceps delivery If they are essential for the one they are equally so for the other

Assuming that all women are infected in the way I have described it is necessary to explain why the great majority have a more or less afebrile puerperium I regard the main safeguards as (1) the natural resistance of the patient herself to infection (2) the nature of the infection—mainly saprophytes but sometimes deadly organisms like anaerobic and haemolytic streptococci (3) the fact that the infection is introduced not into the actual uterus but inside the sac of membranes which is shortly going to be expelled and (4) the rush outwards of liquor amnii—if any remains—after the birth of the child which washes out infection from above downwards

Attempts to sterilize the vagina in midwifery have of course been made many times previously but usually

the results have been worse than when no antiseptic was used at all The work in connexion with the present experiment was undertaken at the Leicester and Leicestershire Maternity Hospital in Leicester during the past twelve months At first 10 c cm of plain glycerin were instilled into the vagina as soon as possible after the patient's admission A short series of cases, however, showed temperatures to be more common than when nothing whatever was done Next were tried pessaries of dimol they also were discarded after being used in fifty cases for rises of temperature were again more frequent than when nothing was used The pessaries also took an appreciable time in melting—about one or two hours after melting a little they became very slippery and frequently were extruded during a pain

Next was tried a 2 per cent solution of mercurochrome in glycerin 5 c cm of this were introduced into the vagina as soon as possible after the admission of the patient and before any vaginal examination had been made The technique is very simple and easy A short length of rubber catheter is inserted as high as possible in the vagina with due aseptic precautions the mercurochrome and glycerin is introduced by attaching a 5 c cm syringe filled with the solution A sterile diaper is applied to the vulva and the patient is kept lying in bed for at least one hour (in those cases not yet advanced in labour) The mercurochrome is repeated each following morning unless delivery is over No irritant effects whatever were observed and there is no danger to the infant's eyes in fact the Eye Department of the Bristol Infirmary has been using a 2 per cent mercurochrome for the past four years to the exclusion of other antiseptics (except in gonorrhoeal ophthalmia)

The investigations of Dr Leonard Colebrook in this country Schottmuller in Germany Schwarz and Dieckman and Harris and Brown in America have shown that the anaerobic group of streptococci is responsible for a large amount of uterine sepsis and that this group is present in the vagina in a considerable number of cases before labour Their work to a large extent discounts the conclusions at present generally accepted as to the harmless character of vaginal organisms present before labour and their non relation to those occurring in the uterus in puerperal sepsis Cultures grown under anaerobic conditions present an entirely different picture They show in a very large proportion of cases a definite relationship between the organisms responsible for severe uterine sepsis and those present in the vagina before labour They provide the bacteriological proof of the necessity of dealing with the vaginal flora Schottmuller in 1923 recorded 72 fatal cases of puerperal infection following delivery due to anaerobic streptococci from a total of 231 fatal cases

Harris and Brown use the following mixture in 7 c cm doses repeated every twelve hours if labour is prolonged mercurochrome crystals 15 grams half strength tinct iodi 5 c cm glycerin 500 c cm They began to try this antiseptic in September 1926 and the reduction in mortality from puerperal sepsis is shown in the following table

	Deliveries	Deaths	Per cent	
July 1924–Sept 1926	1 913	5	0 261	No mercurochrome
Sept 1926 Jan 1930	4 494	4	0 089	Mercurochrome used

This is the reduction in morbidity

	Admissions	Infections	Per cent	
July 1924–Sept 1925	2 194	45	2 05	No mercurochrome
Sept 1926–Jan 1930	5 385	67	1 24	Mercurochrome used

In my own series I used as controls all the cases delivered in hospital during the months of July August September 1930 There were 162 of these and they were in no way selected Mercurochrome in glycerin was given in the next 200 cases and the results are appended

	Temp never above Normal	Above Normal but not 99	Temp 99 but not above	Between 99 and 100°	100 but not above	Above 100° but not Notifiable	Notifiable	Notifiable in uterine origin
Controls (162 cases)	21	48	20	39	10	13	11	8
	12 9 %	29 6	12 3 %	24 0 %	6 1 %	8 0 %	6 7 %	4 9 %
Mercurochrome (200 cases)	55	50	36	23	10	13	13	9
	27 5	25 %	18 %	11 5 %	5 %	6 5 %	6 5	4 5 %

From the preceding figures the outstanding facts are that of the patients who never had a temperature in the puerperium higher than 99° there were 54 4 per cent among the controls and 70 5 per cent among those who had mercurochrome or an increase of 16 per cent for the better When we consider the total number of days that each patient had a temperature the figures are even more striking In each class the patients receiving mercurochrome had a temperature above normal for about half the length of time of the control patients

Table showing Total Number of Days above Normal Temperature for Each Class of Case and the Average number of Days for Each Patient

	Above Normal but not 99	99	Above 99 but not 100	100°	Above 100 but not Notifiable	Notifiable	Uterine Notifiables	Total Days excluding Non uterine Notifiable
Controls (162 cases)	190	111	236	67	89	106	88	781
Average	3 9	5 5	6 0	6 7	6 84	9 6	11	4 8
Mercurochrome (200 cases)	128	125	95	69	77	156	89	581
Average	2 56	3 4	4 1	6 9	5 9	12	9 88	2 93

There is an amazing reduction in the number of days total morbidity for a whole year's working of the hospital as the result of this one addition to the technique Nothing else was changed in the treatment of patients during the time of the experiment and the nursing personnel remained practically the same as during the time of the control cases The procedure is simple and safe requires only a short time to perform and can easily be carried out single handed by any midwife with no addition to her equipment other than a 5 c cm syringe I commend the idea to medical officers of health and maternity hospitals It is far from perfect, but I suggest that if work on these lines were conducted on a national scale and the results were pooled something of very great value would undoubtedly be evolved

Following a recent article in the *British Medical Journal* on the relative bactericidal values of different antiseptics acriflavine in 0 1 per cent solution in glycerin has been used in the next series of cases The results have been notably different as shown in the table below

1 in 1 000 Acriflavine	Temperature never above Normal	Above Normal but not 99°	Temperature 99 but not above	Above 99 but not 100°	100 but not above	Above 100 but not Notifiable	Notifiables	Notifiables in uterine origin
300 cases	48	74	58	71	10	30	9	6
Percentage	16 0	24 6	19 3	23 6	3 3	10 0	3 0	2 0

Here we have 180 cases in which the temperature in the puerperium never exceeded 99° giving a percentage of 60 as against 70 5 with mercurochrome There is however a marked decrease in the notifiable cases of uterine origin only 6 out of 300 or 2 per cent as against 4 5 per cent for mercurochrome All these cases were slight the average number of days each patient had a

temperature above normal being only 9 1 from start to finish with acriflavine and 9 88 with mercurochrome The complete figures are shown in the following table

Table showing Total Number of Days above Normal Temperature for Each Class of Case and the Average Number of Days for Each Patient

1 in 1 000 Acriflavine	Temperature above normal but not 99	99 but not above	Above 99° but not 100	100 but not above	Above 100 but not Notifiable	Notifiable	Notifiable Non uterine Conditions Included	Total Days Non Uterine Excluded
300 cases	230	235	418	69	255	85	55	1,243
Average	31	40	5 88	69	78	94	91	41

Taking 550 cases as the normal year's working figure the following facts emerge The total number of days in the year when patients had a temperature above normal, excluding notifiables of non uterine origin was no antiseptics 2 651 days mercurochrome 1 597 days acriflavine 2 278 days Mercurochrome thus shows a decrease of 39 7 per cent in temperature days, and acriflavine a decrease of 14 per cent

UNDULANT FEVER IN NORTHERN IRELAND

BY

JAMES S BAXTER B Sc M B B Ch

BELFAST

It has been stated by Bigger[1] that undulant fever due to *Brucella abortus* is rare in Ireland only three cases having been reported for the whole country and he infers from this that the strain of *Br abortus* infecting Irish cattle is probably of low virulence for man The following list of cases is published to show that in Northern Ireland at any rate the disease is not so rare as might be inferred from this statement

Within the past two years there have been eight cases of the disease and one of experimental infection The diagnosis of these cases has been made from the clinical features and from the result of agglutination reactions In none of them do we possess the absolute proof of the disease which isolation of the Brucella would have afforded but so far as I am aware in only one case in the British Isles has this been accomplished -

The main features of the cases and the result of the agglutination reactions are here shortly summarized

Case 1 —November 26th 1929 Male boot merchant Headache nausea constipation and pyrexia for three weeks flatulence offensive motions no enlargement of liver or spleen Widal reaction negative for T A B *Br abortus* 1 in 500 (+)

Case 2 —February 2nd 1930 Male aged 42 farm labourer History of headache abdominal pain diarrhoea and fever for four weeks spleen enlarged and tender Widal reaction negative for T A B and C *Br abortus* 1 in 1 250 (+) (Case published in *British Medical Journal* [2])

Case 3 —April 9th 1930 Male aged 47 bank official Ill for six weeks with pyrexia and pulmonary symptoms abdomen distended liver enlarged spleen not palpable Widal reaction negative for T A B *Br abortus* 1 in 5 000 (+)

Case 4 —August 5th 1930 Male aged 45 shipyard official History of headache loss of energy constipation and intermittent pyrexia for one month occasional night sweats spleen palpable well marked relative lymphocytosis (small lymphocytes 38 per cent) Widal reaction negative for T A B *Br abortus* 1 in 5 000 (-)

Case 5 —November 4th 1930 Male druggist History of headache nausea vomiting constipation and typical undulant pyrexia for six weeks pain and tenderness in right iliac fossa Widal reaction negative for T A B *Br abortus* 1 in 250 (-)

Case 6 —April 4th 1931 Male aged 27 motor mechanic History of anorexia abdominal pain constipation and pyrexia of three weeks duration Abdominal tenderness right basal congestion no enlargement of liver or spleen Widal reaction negative for T A B *Br abortus* 1 in 5 000 (+) Temperature fell to normal and has remained so after two injections of normal horse serum intramuscularly

Case 7 —June 19th 1931 Male aged 32 farmer History of headache profuse sweating pain in the neck muscles constipation and pyrexia for a fortnight Rigidity of neck tendon jerks increased Cerebro spinal fluid under pressure but no increase in cells or globulin Widal reaction negative for T A B *Br abortus* 1 in 1 250 (-)

Case 8 —September 16th 1931 Female aged 50 clergyman's wife History of encephalitis seven years ago with apparent perfect recovery Headache malaise pains in legs and pyrexia for about one month spleen not palpable Blood culture under 10 per cent CO_2 was sterile Widal reaction negative for T A B and C *Br abortus* 1 in 2 500 (-)

Dr W Carson of Belfast while carrying out some experimental work with *Br abortus* infected himself with a culture of the porcine type and immediately developed undulant fever of a severe nature In this case the symptoms and fever disappeared after the administration of solganol 0 1 gram intravenously on three occasions

COMMENTARY

In reviewing the salient features of the above cases one is struck by the frequency with which headache constipation and more or less generalized gastro intestinal disturbance are found in this disease One feels sure that a large number of these cases occur unrecognized and pass under the label of gastritis gastric influenza or the like The great preponderance of males over females in this series is also noteworthy

While this list of cases was being compiled an opportunity was afforded me of re examining the agglutination reaction of the serum of some of them The results, although few are given here as they may be of some value in interpreting positive reactions in low dilution found in the routine examination of serums

Case 1 —1 in 25 (-) 1 in 50 (-) 1 in 125 (-) 1 in 250 (-) Twenty one months after illness

Case 2 —1 in 25 (C) 1 in 50 (++) 1 in 125 (+) 1 in 250 (-) Twenty months after illness

Case 6 —1 in 25 (++) 1 in 50 (C) 1 in 125 (C) 1 in 250 (tr) Six months after illness

Case 7 —1 in 25 (-) 1 in 50 (++) 1 in 125 (C) 1 in 250 (++) 1 in 500 (tr) Four months after illness

In one of these cases (Case 1) no agglutination was given This was nearly two years after the illness and the serum during the illness did not agglutinate the organism in a higher dilution than 1 in 500 The other three at varying times less than two years after illness gave very definite agglutination in a dilution of 1 in 125 or higher Case 7 would have been missed if the reaction had not been carried out in higher dilutions than 1 in 25 owing to the presence here of a pro agglutinoid zone

In performing these reactions two sets of dilutions were set up In the first of these the serum as received was used while in the second the serum was first heated to 56° C for thirty minutes to eliminate non specific agglutination Heating the serum had the effect of lowering the titre slightly in each case and the figures given above are all for the heated serum The suspension of *Br abortus* used was the Oxford standard

Note —Since the foregoing was written two further serums have been examined *Case 3* 1 in 25 (C) 1 in 50 (++) 1 in 125 (-) 1 in 250 (-) nineteen months after illness *Case 8* 1 in 25 (C) 1 in 50 (C) 1 in 125 (C) 1 in 250 (++) two months after illness These figures refer to the agglutination performed with the heated serum The unheated serum in each case gave agglutination in a higher dilution

My thanks are due to those physicians of Northern Ireland who have permitted me to include their cases in this list and also to Dr T B H Haslett who kindly performed the agglutination reactions

REMARKS ON SPECTROPHOTOMETRIC CURVES OF BLOOD PIGMENTS *

BY

WILFRID MARSHALL M.A., B.Sc., M.D.

SIDMOUTH

Photographs of blood spectra owing largely to the varying sensitivity of plates to different wave lengths of light give an inadequate idea of the spectrum as a whole. Anyone who has attempted to photograph a mixture of methaemoglobin and oxyhaemoglobin or a so-called neutral solution of methaemoglobin will have recognized the difficulties. The spectrophotometer, which gives accurate measurements of absorption in different parts of the spectrum, would seem provided certain constants are maintained to be free from objection. The curves obtained however, do not represent the blood spectrum seen by the eye and in this respect at least are disappointing. In view of the increasing use of the spectrophotometer as an instrument of precision in analysis and research some observations made in the course of other investigations may not be without interest.

THE INSTRUMENT

The spectrophotometer employed consisted of a Hilger large model constant deviation wave length spectrometer and a Nutting polarization photometer giving a triple field. The large model spectrometer is less convenient to use than the small model, but owing to the greater dispersion it is more delicate, especially for the observation of absorption towards the red end of the spectrum. Its average accuracy over the visible spectrum is about one Angstrom unit. The light source was a 100 c.p. pointolite lamp 63 cm. from the collimator slit. The width of this slit which controls resolution and affects the height and to some extent the width of the absorption bands in the curves should be as narrow as the light source will allow. In most of my experiments it was 0·05 mm. The ocular slit was 0·1 mm. wide and covered wave lengths of 2·1 $\mu\mu$ in the yellow and 1·2 $\mu\mu$ in the blue. The internal diameter of the cells used was 1 cm.

TECHNICAL DIFFICULTIES

When a convenient solution of blood showing well separated oxyhaemoglobin bands is examined spectroscopically the blue of the spectrum appears clear and on *diluting the solution the* α band is the last to go, but when a curve of the absorption coefficients of the solution is plotted the β band of the oxyhaemoglobin appears to be denser than the α band and the limb of the β band towards the blue does not reach zero and is followed by increasing absorption as the violet is approached. The whole curve presents a somewhat tilted appearance. This relative increase in absorption towards the violet is not wholly natural and is difficult to explain. It is obtained with solutions of crystallized haemoglobin and other blood pigments even when these are plotted against dilute serum, but it is not seen in spectrophotometric curves of substances of low molecular weight such as potassium permanganate or even eosin. It was at first thought to be due to the increased scattering of light of diminishing wave length by the large molecules of haemoglobin. But this explanation is not wholly satisfactory. The graphs of absorption coefficients of particulate matter such as suspensions of micrococci or a mastic emulsion are straight lines the inclination of which varies with the concentration, whereas the haemoglobin absorption increases more towards the violet end than visual observation indicates. It may possibly be due to the residual yellow colour of blood solutions. Ordinary colour screens are not sufficiently labile to counteract this effect. Silver colloid solutions which show increasing absorption towards the violet, are more serviceable and I have found dilutions of electrargol especially useful as a control in the spectrophotometry of blood pigments. By using a dilution which will give zero at λ 500 $\mu\mu$ against an oxyhaemoglobin solution a spectrophotometric curve is obtained which presents fairly accurately the blood spectrum seen by the eye.

METHAEMOGLOBIN IN NORMAL BLOOD

Most of my work has been done on ox blood crystallized or more or less purified but near the end of my researches three experiments were made on human blood and these illustrate the value of curves of this type. Blood was obtained from the ears of three different persons in the usual way and was diluted to a convenient concentration for examination. To 5 c.cm. of the dilution was added one drop of strong ammonia solution and to another 5 c.cm. one drop of water. The two solutions were straightway placed in identical cells, the ammoniacal dilution was put in the beam of the polarized light and the neutral solution in the non-polarized beam of the spectrophotometer. The difference in the absorption coefficients was then taken. On plotting the curve showed slight rises in the red and in the position of the two oxyhaemoglobin bands. From an analysis of the curves of oxyhaemoglobin and of acid and alkaline methaemoglobins it is difficult to avoid the conclusion that in these three individuals a trace of methaemoglobin is normally present in the blood. Whether this is universally the case further research for which I have not at present the opportunity will show. There seems however, no obvious reason why oxyhaemoglobin and methaemoglobin should not normally exist in a balanced state and a minute concentration of methaemoglobin be *in equilibrium with the oxyhaemoglobin of normal blood*.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

SURVIVAL FOR SEVEN DAYS AFTER RUPTURE OF AORTIC ANEURYSM

Rupture of an aneurysm of the aorta is not a common occurrence but survival for seven days thereafter must be very rare. Only the post-mortem findings in the following case could have led me to believe that such a happening was possible.

The patient a man aged 65 years first consulted me on October 15th, 1931, complaining of pain radiating down the inner aspect of the left thigh from the vicinity of the saphenous opening. This I diagnosed as an anterior crural neuritis and treated it with sodium salicylate and potassium iodide therewith affording considerable relief.

On October 22nd I was called to see the patient who informed me that as he was strolling round his room he suddenly sat down on the floor. He felt no sensation of discomfort but in view of the fall he felt alarmed and went to bed. Two days later it was evident that he had had an enormous haemorrhage into the tissues of his left abdominal wall. The skin from the spine to the mid-axillary line and from the crest of the ilium to the scapula was black with effused blood. The left iliac fossa was occupied by a tense mass which stretched up under the costal margin. The only symptom referable to the abdomen was a troublesome hiccup which persisted till the end. He survived till October 28th (seven days) when he died suddenly after some slight movement in bed.

Post-mortem I found in the abdominal cavity a large quantity of serous fluid and a lesser though considerable

quantity of free blood Just above the bifurcation of the aorta was a small aneurysm containing fibrin deposit to a depth of three quarters of an inch Through a small rent in its postero lateral wall the finger could be passed over the psoas muscle into an enormous mass of blood clot occupying the whole of the iliac fossa and extending upwards to the diaphragm displacing the heart to a position practically in the mid line This mass was extraperitoneal and my conclusion was that death only occurred when under the strain of some exertion the peritoneum gave way and blood escaped freely into the abdominal cavity

TERATOMATOUS CYST OF THE OVARY DISCHARGING VIA THE UMBILICUS

A multipara aged 41 was admitted to St Columba's Hospital Hazaribagh India on October 14th 1931 complaining of abdominal discomfort and discharge from the umbilicus The patient said that she had had a lump for a month and a discharge from the navel for a week otherwise she was well

On examination a yellow semi fluid discharge was seen to be coming from the umbilicus Midway between the pubis and the umbilicus a swelling of cystic consistency was palpable It was the size of two fists The tumour appeared to be attached to the deeper layers of the abdominal wall The general condition of the patient was fairly good and examination revealed no other abnormality The temperature was 98 2° F and the pulse 86

About an hour after examination of the abdomen a large amount of discharge resembling thickly curdled egg and milk was passed via the umbilicus On the day after admission the patient began to run a temperature fluctuating from 98 4° to 101 6° and the pulse rate increased to 110–120 She had little pain Within the course of the next week the discharge lost its curdled appearance and became fetid and haemorrhagic

OPERATION

On October 28th operation was performed A median subumbilical incision was made and was then carried upwards so as to encircle the umbilicus The peritoneum was exposed and a probe was then passed along the umbilical fistula The probe appeared to go down to the pelvis On incision of the peritoneum a yellowish white walled cyst was exposed the upper part of which was adherent to the peritoneum of the abdominal wall The probe was felt to be passing down towards the pelvis in a plane posterior to the cyst The omentum which was very adherent to the cyst was freed after some difficulty and it then became apparent that the cyst was of pelvic origin for the Fallopian tube was to be seen stretched across part of the tumour

The cyst was rotated and partially expressed through the abdominal wound It was then found that there was a second cyst lying posterior to and below the first one The probe passed posterior to the first one down to the second Both cysts had burrowed between the layers of the right broad ligament and though lying adjacent to *each other* did not intercommunicate The broad ligament was divided and the two cysts rotated upwards The track leading from the umbilicus to the lower cyst was then traced from below upwards It was about three and a half inches in length It was found to be a fibrous canal within a sheath of omentum the lower two inches in posterior to the first cyst the upper one and a half inches were firmly adherent to the peritoneum of the anterior abdominal wall This portion of the peritoneum had to be removed with the canal and the umbilicus The uterus was small and the left ovary and tube were normal Apart from the omental adhesions in the region of the cysts there were *no* other signs of previous peritonitis

On examination of the cysts the anterior one was found to contain a bundle of black hair cartilage and thick sebaceous yellow material The posterior one contained a mass of white hair bone cartilage and a quantity of haemorrhagic fouls clotted

St Columba's Hospital Hazaribagh India RUTH BOCOCK

A CASE OF COW-POX OR VACCINIA

On October 1st 1931 a farmer's wife visited me complaining of some water blisters on her fingers with swelling of her hands She said that six days before she noticed little red spots on her fingers which within the next day or two became pimples Three days before I saw her she had noted the pimples changing to water blisters which gradually increased from pin point size until they were about the size of a threepenny piece At this time she attended the surgery The patient also said that she had been picking brambles a week before the blisters appeared and had scratched all her fingers especially those of the right hand This had not prevented her attending to the milking of the cows one of which had some blisters and crusts on its teats The latter she treated by removing the crusts with olive oil and gently milking After this attention to the cow she was always careful to cleanse her hands thoroughly for fear of anything infectious

On examination the patient was flushed temperature 100° F tongue was dry and furred She complained of feeling shivery and cold with sweating at night There was headache loss of appetite nausea and constipation altogether she looked and felt out of sorts and had been so for the past four days Both hands and forearms were oedematous and reddened up to the elbows On the fingers of each hand (most marked on those of the right hand) were groups of vesicles varying in size from a pin point up to about the size of a threepenny piece Some of these the older vesicles had burst and were exuding serum The vesicles were surrounded with dark red areolae with erythema beyond this The blisters were most marked on the forefingers of each hand Papules also varying in size were present on the other fingers on the posterior aspect of the upper arms and on the calves of the legs This eruption was very itchy There was a faint generalized erythema over the body Of the larger intact vesicles some were filled with a greyish jelly like material while older ones were beginning to dry and get black in the centre Adenitis was present in the glands at the bend of the elbow and in both axillae

The patient was advised to go to bed to keep on a light diet and to pay attention to the bowels Spirit dressings were applied to the vesicles on the fingers She was given a soothing lotion to apply to the erythematous papular part of the eruption—that is on the hands forearms arms and legs etc The temperature remained above normal till three days later oscillating between 99° and 100 5° By that time October 5th the erythematous papular part of the eruption had faded with absorption of the oedema in the left hand and forearm (the lesser affected) while the oedema in the right hand and forearm had greatly lessened There were no new lesions to be seen The vesicles were now drying up and crusting had appeared on the older ones—that is those on the right forefinger The ante cubital and axillary adenitis had abated On October 7th the temperature was normal and all febrile symptoms had disappeared The patient was allowed up and when seen on October 9th all the vesicles had crusted and darkened There was no oedema in the right hand or forearm Within the next few days the crusts began to be shed and at a final visit on October 14th there were no crusts to be seen and all the lesions had healed

COMMENTARY

The above no doubt was a true case of cow pox The woman had prepared her fingers for inoculation by the scratching caused by bramble gathering The treatment of the sores on the teats of the cow expressed lymph on to the fingers resulting in infection with extremely successful multiple vaccination The general febrile symptoms now followed as a sequel The sores on the teats of the affected cow consisted of numerous vesicles some of which were oozing serum while others had crusted In conclusion I should state that the woman had never been vaccinated

SYNTHETIC ANTI MALARIAL DRUGS

At a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on January 7th, with Professor J G Thomson in the chair Professor W Schulemann director of the pharmaceutical laboratory of the dye industries at Elberfeld, Germany, lectured on synthetic anti malarial preparations

After an account of the early work on quinine and the testing out of salvarsan and stovarsol as anti malarial drugs, Professor Schulemann said that in 1924 he, with two colleagues, Schonhoff and Wingler carried out certain experiments on methylene blue and later applied some of the experience gained with this substance to the quinoline group Amino quinoline was found to have a marked influence on protozoal infection in canaries This knowledge was made the basis of further work and by full co operation between chemists and physicians these beginnings were developed the position of the amino groups in the chemical constitution was changed side chains were varied and much other work was done He showed a large number of diagrams illustrating the chemical formulae The action of the compounds was tested out in animal experiments and what was now known as plasmoquine with the formula $C_{19}H_{29}ON_3$ and molecular weight 315 was selected for practical clinical investigation The formula compared with that of quinine $C_{20}H_{24}O_2N_2$ and the molecular weight of quinine was 324 Plasmoquine was at first only found effective in malaria induced in general paralytics (Sioli, 1925), and this work had not led to the production of a substitute for quinine Plasmoquine was a synthetically prepared anti malarial drug differing from quinine in its therapeutic properties The first clinical experiments with pure plasmoquine and plasmoquine combined with quinine were carried out by Muhlens by Manson Bahr in this country and by others elsewhere The parasites of tertian malaria reacted more strongly to quinine than did those of quartan malaria while quinine had hardly any effect on the parasites of subtertian malaria These variations indicated that the parasite in its different stages reacted to drugs in different ways and this was confirmed by the investigations carried out with plasmoquine He instanced the work of Sinton Knowles Wallace and others on the relapse rate following plasmoquine treatment It had been shown that with plasmoquine alone or combined with quinine the relapse rate in tertian malaria could be reduced to between 2 and 5 per cent in subtertian malaria the results appear to have been quite so satisfactory, [illegible] also there seemed to be [illegible] relapse rate [illegible] blue does not reach zero as did not sulphomethosing absorption as the violets although here whole curve presents have been a certain reduction in the relative me[illegible] Plasmoquine had practically no effect on wholly [illegible] but it definitely destroyed the [illegible] tertian schizonts but it definitely destroyed the gametocytes after a few days The early view that plasmoquine could inhibit the formation of gametocytes had not been confirmed on the other hand the work of Barber Komp Newman Roberts Jansen and others went to show that even minimal doses of plasmoquine which were too small to cause the subtertian gametocytes to disappear nevertheless sufficed to render them incapable of infection This action of plasmoquine naturally raised the question of the possibility of malaria control by sanitary measures whether by means of plasmoquine it was possible to prevent the anopheles from becoming infective by giving the drug to the human host Barber had written to him a short time ago from West Africa stating that he had succeeded in putting this theory into practice and intended to publish his results in the near future In actual practice of course one must never lose sight of the fact that this control would only be possible in exceptional conditions but rarely could a whole population be treated so effectively by means of drugs that every gametocyte carrier would be included, and thus render it impossible for the mosquito to become infected from the human

Professor Schulemann went on to say that the only property of quinine was to suppress the symptoms of infection, not to prevent its occurrence The latest work of James, on the other hand had shown that plasmoquine, in doses of 0 06 gram daily for a period of six days, might be considered as a chemoprophylactic The scientific importance of this work had already been definitely established because it had drawn attention to many new aspects of the problem which revealed the way to further investigation It ought to be possible to discover new drugs, differing both from quinine and plasmoquine which might attack at other points the cycle of development of the malarial parasite Recent work in the experimental laboratories at Elberfeld went to show that these considerations were justified Two experimental chemists there had succeeded in forming a new compound to which the name of 'erion' had been given This substance differed in its action from plasmoquine in spite of certain chemical relations It was believed that it would be effective against the schizonts in the same way as quinine Supplies of the substance had been placed in the hands of a number of workers in the Tropics and sub Tropics, and the reports so far obtained showed that it was effective against malaria acting on the schizonts, but having no effect upon the gametocytes It seemed to offer advantages in respect of dosage and duration of treatment, and also appeared capable of materially reducing the number of relapses after treatment

In conclusion, Professor Schulemann made grateful acknowledgement of the help he had received from workers in various parts of the British Empire this had been a constant stimulus

Discussion

Sir Henry Dale said that the lecture represented a real addition to the knowledge of most of those present They had known more or less what plasmoquine was but until that evening they had naturally supposed that the investigation on this synthetic preparation started with the attempt to build up something more or less like quinine They now learned that, on the other hand it had really started with work on methylene blue Professor Schulemann with the most admirable modesty, had put forward a small list of substances which had been tried out in arriving at plasmoquine, but if instead of giving them a short list [illegible] of AQRTIC ANEURISM the whole series of Rupture such as that, he had given the compounds which must have been tested at Elberfeld before plasmoquine was reached a larger room than the one in which they were meeting would have been necessary for the display of his diagrams Professor Schulemann had not suggested that this research proceeded in a perfect logical progression he knew that all such researches had to proceed, to a large extent by mere trial and error Ehrlich was ready to admit that in this work on chemotherapy there was a certain element of luck but there was much more than luck and those present that evening had appreciated what real scientific enterprise could do, the kind of patient careful work which did not claim too much at any stage and which in the end arrived at success

Colonel S P James said that plasmoquine was the first effective anti malarial remedy which had been prepared synthetically in the laboratory and Professor Schulemann's decision to come to England and explain to the Royal Society of Medicine the exact history of its discovery was a friendly gesture which would be widely appreciated The discovery was noteworthy not only because plasmoquine was a new and very potent anti malarial weapon but because an observation of its action on the different stages of the malarial parasite had led to an important

change in the ideas and aims regarding the chemotherapy of malaria Formerly it was generally believed that the chemotherapeutic problem of malaria was a single problem that all that it was necessary to do was to find a drug which would act more effectively than quinine in curing malarial attacks It was now realized that the chemotherapeutic problem of malaria included four separate phases of research each of which must be considered as quite distinct The first was the problem of the sporozoites the second the problem of the asexual parasite the third that of the sexual forms and the last the problem of the forms responsible for relapses Perhaps in the future a single drug would be found which would act equally well on all these stages of the parasite but so far as was known at present the conclusion which must be stated from the action of quinine and plasmoquine was that for each of these separate stages a different drug might be found For destroying the sporozoites plasmoquine was the only known drug to be effective and even plasmoquine for this purpose was not entirely satisfactory According to the latest experiments at Horton in an intensely malarious place in order completely to protect oneself by taking plasmoquine it would be necessary to take a daily dose of 4 cg and this if prolonged over a considerable period would produce toxic symptoms in certain cases With regard to the asexual parasites quinine was already available In the sexual forms plasmoquine acted excellently and in doses much smaller than those effective against the sporozoites Finally with regard to the forms which were responsible for relapses unfortunately up to the present no known drug had any real effect in the prevention of relapses Professor Schulemann had mentioned some reports in which it was stated that the relapse rate after a course of plasmoquine was less than after a course of quinine He could not help feeling however that the observations recorded in those reports were open to another interpretation and it was quite certain that as regards malignant tertian malaria at any rate plasmoquine was not more effective for preventing relapses than was quinine Colonel James showed a chart illustrating five cases of malignant tertian malaria which had been treated at Horton In all these cases a course of plasmoquine either given alone or combined with quinine failed entirely to prevent them from relapsing The chief difficulty in assessing the value of new antimalarial drugs was that in each of the species several different varieties or strains had to be considered some of which must be described as being quite virulent while others were mild Up to the present at Horton seven strains had been studied—two from India one from West Africa one from Sardinia and three from Rome Quinine in very small doses availed against the Indian strain without any difficulty and in moderate doses against the West African strain But in the case of the Sardinian and Roman strains the results were quite different These were refractory to quinine in very large doses Before venturing to say that a new antimalarial remedy possessed remarkable curative properties one must ascertain whether or not the cases in which it was being tried were infected with a strain of the parasite which could perhaps be as easily cured with moderately small doses of quinine In the future what seemed to be needed for chemoprophylaxis was a drug with the same action as plasmoquine but less toxic and for chemotherapy a drug which in moderate therapeutic doses for a short period would not only cure the attacks of the disease but effectively prevent all relapses He gathered that one or more new drugs might issue from Elberfeld and one looked forward to these with great interest

Professor WAKEFIELD YORKE contested Professor Schulemann's statement that quinine had no action upon the gametocytes He had been very much interested in Colonel James's remarks because he had held the view for a long time that if any really substantial advance in chemotherapy were to be made the biological side of the question must not be burked It should not be forgotten that in quinine they probably had one of the most remarkable drugs ever known and it did not reflect great credit upon them that at this late stage in the history of the subject so little was known of its action and of the factors whereby its action was governed

Sir MALCOLM WATSON spoke of mosquito control in tropical and subtropical areas and said that as early as 1909 quinine in his hands had proved to be a broken lance The researches of Professor Schulemann had given workers in the Tropics great encouragement but for his own part he would have more faith in a drug which destroyed the schizonts than in one which acted simply on the gametocytes

Dr P H MANSON BAHR mentioned that he had read the first paper on plasmoquine in this country at the Royal Society of Medicine five years ago Plasmoquine acted in a different manner on the three species of malarial parasite as they produced their clinical effects in man But it was necessary to beware of drawing inferences from clinical work in a temperate climate as to what would happen under the enervating conditions of a tropical one He had been using plasmoquine perhaps *ad nauseam* for the last five years and he had had more gratitude from his patients for using plasmoquine than in the case of any other drug this referred mostly to people infected with benign tertian malaria He considered plasmoquine was highly specific for the *Plasmodium vivax* It was much less specific for the merozoites of the subtertian It had its most remarkable action on the gametocytes There were other clinical applications of these new compounds One of the great difficulties of quinine administration in the Tropics was its bitter taste Plasmoquine was practically tasteless Children tolerated it better than adults and in children it did not so readily provoke cyanosis and other toxic symptoms The second great clinical application of plasmoquine was in pregnancy He had had five cases of pregnancy in women who had been sent home because of the inadequacy of quinine to cure their infection two of them were infected with subtertian malaria and were in a very critical state He had treated two of the subtertian cases two of the benign and one of the quartan all at about the sixth month of pregnancy Not only had these women not had any more relapses but they had borne perfectly normal children He also referred to the use of plasmoquine in blackwater fever where it appeared to have a useful effect in the convalescent stages As time went on it did not appear necessary to give such large doses of plasmoquine as was generally thought There was undoubtedly an idiosyncrasy to plasmoquine as to quinine What constituted this idiosyncrasy it was difficult to say Professor ROBINSON touched on some aspects of the new work which were of interest to chemists and Dr M A ARAFA gave an account of some experiences in Cairo where he had used plasmoquine intravenously he had found this method disadvantageous intravenous medication producing quite an appreciable fall in blood pressure

Professor SCHULEMANN in reply mentioned that about 12 000 different preparations had been studied in the course of the research on this problem Methylene blue had been taken as the starting point because it offered the possibility of changing relatively easily the chemistry of the preparation whereas the chemistry of quinine was very hard to work upon He did not know of any near relation between chemical constitution and therapeutic effect He thought a very exact distinction must be made in the number and percentage of relapses as between the tertian and subtertian conditions

Reviews

A GERMAN TEXTBOOK OF MEDICINE

The thirtieth edition of Strumpell's famous work on the *Special Pathology and Therapy of Internal Disease*, revised since the author's death in 1925 by Professor SEIFFARTH, has now been translated into English by C. F. MARSHALL and C. M. OTTLEY under the title of *A Practice of Medicine*.[1] It runs into three volumes, and covers the whole field of medicine, including tropical diseases and neuroses but not mental diseases or dermatology. There is an appendix on poisons.

Although it has in one sense two authors, the work has essentially the qualities, and to some extent the weaknesses, of a one-man book. Throughout its pages we have the benefit of the knowledge, experience, and point of view of a great physician. The note throughout is clinical: the descriptions of signs and symptoms defy criticism, and are especially stimulating to read as an antidote to the modern medicine of blood tests, cerebro-spinal fluid examinations, and gastro-photography. Although we agree that medical diagnosis must always rest on clinical knowledge, which can never be replaced by laboratory technique, yet some of the more important recent advances which have proved their value are, in our opinion, inadequately referred to. Especially is this the case in the section on kidney disease, in which the methods of blood-chemistry receive only the barest mention. The chapter on irregularities of the heart is particularly weak, and leaves the reader with only a vague impression as to the modern views on their mechanism, classification, and treatment. In other sections also, there is too much loose talk of "irregularity" and "arrhythmia," which, as every modern student knows, may mean anything or nothing, though those with a knowledge of German will realize that the latter term is often used as an abbreviation for arrhythmia perpetua. On the other hand, full credit is given to the value of radiological methods, and many sections are well illustrated by reproductions from x-ray photographs.

We have already mentioned the excellent clinical descriptions, and in this respect the sections on fevers, on diseases of the chest, and on diseases of the nervous system (the third volume is entirely devoted to the last-mentioned) are of outstanding merit, while tropical diseases are described with detail rarely found in a textbook of medicine. The illustrations throughout are abundant and excellent. The German point of view is not so prominent as to lessen the value of this work to English users, though there is a tendency towards a firmer belief in the pharmacopoeia than is common among modern British physicians.

The translation has been well done in the sense that the English throughout is good, fluent, and readable, but there are words which, though not incorrect in this language, are hardly ever used, and might have been rendered more freely. For instance, arrhythmia perpetua is used as including auricular flutter and fibrillation, angina is used in a general sense for all inflammatory conditions of the tonsils and palate, and *Reststickstoff* is literally translated as *residual nitrogen* instead of *non-protein nitrogen*—the usual English and American equivalent. Perhaps this is because both the translators are surgeons.

Typhus for typhoid on page 35 is of course a slip of the pen arising from the different use of the words in the two languages.

While we welcome, therefore, the translation of this truly remarkable and universally recognized German text-book, we cannot but regret that all its sections have not been brought equally up to date, and must admit, however reluctantly, that the days of single authorship of textbooks of medicine are passing or have passed. That it may need several writers to revise in 1931 a textbook written by one author in 1883 should be looked upon as a sign of advance rather than retrogression.

MIDWIFERY BY TEN TEACHERS

The fourth edition of the popular *Midwifery by Ten Teachers*[2] will be welcomed by all who are interested in the teaching of obstetrics in this country. Previous editions have served the useful purpose of preparing students for their examinations, and the new edition is a great improvement upon the old. The book deserves its wide popularity, for it is permeated with an atmosphere of sincerity, and we feel that the authors all have the welfare of students at heart. One advantage of having a number of contributors to a book of this kind is that there can be no violent prejudice if the contents represent the considered judgement of ten experienced teachers. On the other hand, with such a galaxy of talent, the present edition might perhaps have been made much more ambitious, and there is no reason why, with modification and adjustment, the next should not rival the Continental and American standard works. At present the book falls short of this. The general arrangement might be bettered. Normal pregnancy, labour, and lactation should be at the beginning of the book. To place abnormal pregnancy with the description of such conditions as icterus gravis gravidarum and ectopic gestation, before normal labour gives a wrong outlook on obstetrics to the beginner, who should have impressed upon him, above all things, that pregnancy and labour are usually physiological processes. Intermittently there are outcries against meddlesome midwifery, and one of the surest methods of combating this acknowledged evil is to instil into students the essentially physiological nature of pregnancy and parturition. The first chapter on menstruation and embryology has not been revised with sufficient care: there is no mention of the recent specimens of early human ova, so that some of the statements are not only obsolete but inaccurate. This chapter requires thorough overhauling for each edition.

Some of the old blemishes reappear. The same definition of the ammonia coefficient of the urine remains, and the explanation of the rotation to the front of the occiput of the after-coming head of the breech is as unconvincing as ever. The arrangement of the material in the chapter on the diagnosis of pregnancy is disjointed. In the description of the treatment of heart disease complicating pregnancy no distinction is drawn between the different cases of primigravidae and multigravidae. In the former, every effort should be made to allow a living child to be born at term, in the latter termination of pregnancy should be practised more often, particularly if decompensation developed in previous pregnancies. Chorea gravidarum is described as related to rheumatic fever, the modern view is to deny any such association. One of the chief defects of the book is the inadequate consideration of deep transverse lie of the head, a condition which has never received sufficient recognition in this country; it is included under occipito-posterior presentations, though in most cases the occiput is originally anterior. The condition might well be emphasized by separate

[1] *A Practice of Medicine*. By Professor Adolf Strumpell. Twenty-ninth and thirtieth editions by E. Seyfarth, D.Med. et Phil. Authorized translation from the thirtieth German edition by C. F. Marshall, M.Sc., M.D., F.R.C.S., and C. M. Ottley, B.M., F.R.C.S. Vols. i., ii., and iii. London: Bailliere, Tindall and Cox. 1931. (Pp. xxiv + 2,356; 395 figures; 17 plates in the three volumes. £5 5s. net.)

[2] *Midwifery by Ten Teachers*. Under the direction of Comyns Berkeley. Edited by Comyns Berkeley, J. S. Fairbairn, and Clifford White. Fourth edition. London: E. Arnold and Co. 1931. (Pp. xi + 740; 297 figures, 4 plates. 18s. net.)

description for it often gives rise to delay in the second stage of labour The use of a hot lysol douche to stimulate a sluggish uterus in the first stage of labour will not be generally accepted and it is more exact to administer pituitrin in unit doses rather than in cubic centimetre doses

Some chapters are very well written Particular mention should be made of the chapter on the management of labour with disproportion the author deserves special praise for the article is an admirable piece of work which should be read by all who practise obstetrics The new *Ten Teachers* will continue to assist students in getting through their examinations for this edition is better than the last Nevertheless the senior editor might with advantage arm himself with autocratic powers and insist upon a more drastic revision for the next edition

THE NATURE OF GENIUS

A book which is at the same time both interesting and irritating is *The Psychology of Men of Genius*[3] by ERNST KRETSCHMER professor of psychology and neurology in the University of Marburg translated from the German by Dr R B Cattell It is interesting because it attempts to elaborate still further the thesis (set out in the author's previous work *Physique and Character*) that there is an intimate and inevitable relation between human form and human nature and character and to establish that this thesis holds true in a special field and also because many of the individuals he chooses as the subjects of analysis are persons whose lives have a curious fascination It is irritating because in the pursuit of his argument the author constantly uses the two sophistical devices of begging the question and of special pleading If a man first carefully rigs his definition of what he means by a person of genius and then proceeds to exclude whole classes of persons who would appear to come within the definition because they do not happen to suit his purpose or about whom he simply states that he has not enough information and if further among those who are left he chooses his examples arbitrarily and even with regard to these states that he will not accept their biographies as material but will read beyond the specious phrases in which the facts are dressed up he can of course seem to prove anything It is unfortunate the translator admits from the point of view of the psychologist that he has omitted fully to set out the raw material of his statistical conclusions and has not set off his results against a control group of normal persons The conclusions broadly are that genius is closely allied to insanity in its two main forms that different kinds of genius are intimately associated with the several varieties of bodily form feature and physique and that it is the mixture of the Nordic and the Alpine races of mankind which is predominantly concerned in its production

The author's standpoint and some of his methods are peculiarly German It is quite natural and proper that his two chief analyses should be those of Goethe and Schiller But it is strange that while there is an extended consideration of Holderlin as an inspired poet Shakespeare is mentioned only once (and that quite incidentally), and that an equally elaborate analysis is made of Robert Mayer's character as that of a man of science while Newton's name occurs just once (and then in a list of eminent men who were mentally diseased!) and that Charles Darwin is in the text not mentioned at all though his portrait appears among those of the masters at the end of the volume Professor Kretschmer has certainly rendered service to psychiatry by some of the distinctions he has drawn and the suggestions he has made but whatever basis of truth may ultimately be found to lie below the conclusions of this volume those conclusions cannot be accepted as established by his presentation of the case therein

THE VEGETATIVE NERVOUS SYSTEM

The ninth volume of the series of research publications issued by the Association for Research in Nervous and Mental Disease consists of a group of papers on *The Vegetative Nervous System*[4] read at the meeting held in December 1928 It is a pity that these volumes do not appear within a more reasonable time from the actual reading of the papers The book is divided into six sections which vary somewhat in their interest The first is a well balanced retrospect by Dr Timme whose name is sufficient to guarantee its accuracy The second section is devoted to morphology and deals with the development of the autonomic nervous system the central representation of the sympathetic nervous system and the innervation of the muscle spindle etc The third section is concerned with physiology The chapter on the somatic and visceral connexions of the diencephalon is one of the best in the book if not the best our knowledge of the nuclei of the thalamus and their connexions has advanced considerably during the last twenty years The fourth section discusses the experimental point of view and deals with the parasympathetic control of muscle tonus the regeneration of the sympathetic nerve fibres the nerve supply of the cerebral blood vessels and the cerebral circulation The fifth section deals with clinical aspects of the vegetative nervous system In discussing the emotions and the clinical manifestations in the involuntary nervous system some space might well have been given to the relation of emotional dulling in schizophrenia to disorder of the involuntary nervous system (apart from the emotional upsets in the anxiety states) and to the lack of correspondence between the emotional display in hysteria and the psycho galvanic reflex manifestations thereof In the same section we find chapters devoted to the cortical influence over the sympathetic system the relation of the vegetative nervous system to hyperthyroidism tumours of the vegetative nervous system and diencephalic autonomic epilepsy The final section is on treatment and it includes a consideration of the effects of sympathectomy in angina pectoris and the relief of pain in angina by paravertebral alcohol block of the upper dorsal sympathetic rami Generally speaking the work is so well done that we have little but praise for it

DISEASES OF THE GUMS AND ORAL MUCOUS MEMBRANE

In his preface to the fourth edition of his work on *Diseases of the Gums and Oral Mucous Membrane*[5] Sir KENNETH GOADBY reminds us that focal sepsis is now blamed for wellnigh every variety of infection while not long since it was practically disregarded The truth he thinks lies midway and to emphasize the point cases showing the danger of drawing conclusions from incomplete investigation are cited The cases indeed add

[5] *Diseases of the Gums and Oral Mucous Membrane*. By Sir Kenneth Goadby Fourth edition Edited by P Ward Wilson DPH Manchester Oxford University Press 1931 (Pp 252 figures £2 2s net)

greatly to the value of what we think the most important part of the book—namely, the exposition of the author's methods of clinical and laboratory investigation in elucidating the part that dental sepsis may be playing in any particular case. Perhaps the most striking point in this connexion is the value placed by the author on the use of polymorphonuclear differentiation in deciding the existence of chronic forms of infection. In Sir Kenneth Goadby's opinion the further study of vitamins and deficiency diseases has fully corroborated the theory that dental caries and 'pyorrhoea alveolaris' are primarily deficiency diseases, but frankly, we do not find that this conception has greatly modified his views. In criticizing nomenclature, he pertinently suggests that if we use "odontalgia" for "toothache" we ought to substitute "periodontalgia" or "alveolalgia" for the homely Saxon 'jawache'. He is not always clear in his diction and, as an instance we fail to grasp his point when (p. 417) he says 'a limited number of apical "radiographic holes" prove to be quite other than cavities, and are hard bone," and refers us to a discussion at page 136, which we confess we cannot follow.

This work answers fully to its title. We think there is no disease of the gums or oral mucous membrane that is left undescribed, and most are illustrated, but its chief value is as an epitome of a life's work on dental sepsis.

CHEMISTRY OF NUCLEIC ACIDS

Dr. P. A. Levene is one of the most tireless and, at the same time, one of the most accurate workers in the field of biochemistry. His name is associated particularly with two fields of research—investigations of the chemistry of the nucleic acids and of the lipoids. The monograph by LEVENE and BASS entitled *Nucleic Acids*[6] must therefore command respect as an authoritative statement, by a master, of the present position in his own field of research. Levene's work has dealt with the static rather than with the dynamic side of biochemistry—with the establishment of chemical constitution rather than with the study of the changes which substances undergo in the living cell. Such work of course is necessary to make the study of cell dynamics even possible.

The nucleic acids have an interest even for the least chemically minded medical man, in that they are the parent substances of uric acid and that among the purine bases are the drugs caffeine and theobromine. Levene and Bass's monograph is a comprehensive survey of the work so far done in this field—much of which was performed by Levene himself—and will be welcomed by all workers who are even remotely interested in nucleic acid chemistry.

NOTES ON BOOKS

A work entitled *Communicable Disease Control*[7] represents the report of a committee of the Public Health Section of the White House Conference on Child Health and Protection summoned by President Hoover. The purpose of the report as stated in the preface is, first, to point out the importance of communicable diseases in children, secondly to review the current control practices, thirdly to recommend those practices which seem most valuable and fourthly to suggest the fields in which further studies are most urgently needed. Tables are given showing (1) the communicable diseases which accounted for the greatest number of deaths among persons under 20 years of age in 1926, 1927, and 1928 in the registration area of the United States, (2) the annual incidence of the ordinary contagious diseases reported by the State health officers from 1919 to 1928 and (3) their seasonal prevalence. A brief account of the specific therapy or prophylaxis in some of the large cities of the United States is followed by the procedure recommended for the control of individual diseases, which has been based on consultations with more than fifty experts throughout the country.

The well illustrated and well produced account of comparative dental pathology entitled *Abnormal Conditions of the Teeth of Animals in their Relationship to Similar Conditions in Man*[8] is the outcome of a series of four lectures by Sir Frank Colyer delivered last year in Liverpool, Glasgow, Birmingham and London. They deal with injuries to the teeth and jaw, caries and hypoplasia of the teeth, progressive destruction of the tooth sockets and positional variations of the teeth. The author has amassed a very large series of examples from all parts of the world and drawn from a large number of different species of mammals—wild, captive and domesticated. *The result is that the volume is a treasure house of facts* not only for the dentist and those directly interested in dental problems but for the zoologist and the comparative pathologist as well.

The second volume of *Contemporary Thought of Germany*[9] which was anticipated in our notice of the first (March 21st 1931, p. 501) shows the illuminating qualities of its predecessor—exceptional lucidity, a masterly grip of the subject, and remarkable power of condensation (there are only about 200 pages). In this volume Dr. TUDOR JONES attempts to give a synoptic view of the most important contributions of the schools of scientific, philosophical, and sociological thought in Germany to-day represented among others, by Rickert, Husserl, Vaihinger, Jung, and Max Weber. There is a chapter on the philosophy of life and another on the philosophy of religion. The chief impression left by this survey is that with the decline in speculative metaphysics many German scholars are meditating on the reconciliations necessary to a new religion consistent with the verified conclusions of the sciences.

In *The Scientific Detective and the Expert Witness*[10] which is the second edition of a shorter one entitled *The Expert Witness* published in 1923 Dr. C. AINSWORTH MITCHELL, editor of *The Analyst*, not only describes how evidence should be given but how it should be obtained by scientific methods. Thus an account is given of finger-prints, handwriting and chemical analysis. Many cases are quoted throughout and in the last chapter on the application of expert evidence to history the identification of Mary Queen of Scots' handwriting is lucidly discussed by the author who, from his examination of the 'Casket letters'—so called because they were said to have been taken from a casket left by Bothwell—concludes that this unfortunate Queen did not write them, and ought not to have been condemned on the evidence stated to be contained in them. Students of medico-legal medicine will find these pages both pleasant and profitable reading.

The *Transactions* of the Eighth International Congress of the History of Medicine held at Rome last September (see *Journal* 1930, ii, 609) have recently been issued under the editorship of the president, Professor Pietro Capparoni, to members of the congress. They form a fine volume of nearly 600 pages, limited to 350 numbered copies.

PREPARATIONS AND APPLIANCES

A GESTATION PERIOD CALCULATOR

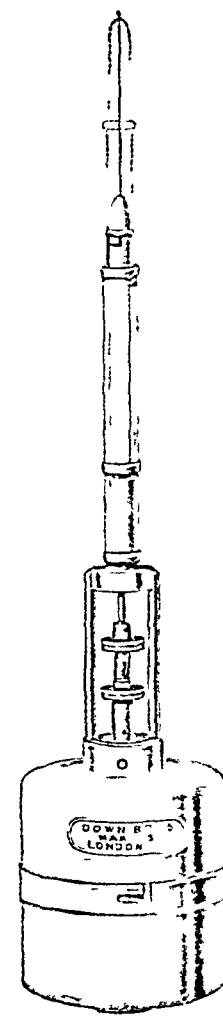
Professor DANIEL DOUGAL (Manchester) writes: We are all familiar with the obstetric tables which show at a glance the expected date of delivery and are based on Naegele's method of counting 280 days from the first day of the last menstrual period. In practice they are seldom used as it is quite easy and sufficiently accurate to do a small sum in mental arithmetic by counting back three months from the commencement of the last period and then adding seven days. The small inaccuracy of this simple method is due to the fact that when certain months are included in the period of gestation only four, five or six and not seven days require to be added in order to make up a total of 280 days. In routine ante-natal work the expected date of delivery is usually determined by the method just described but a good deal of time is wasted in calculating the number of weeks the patient is pregnant at the time of examination and it is here that some form of gestation period calculator comes in useful.

The illustration shows one which Messrs. Mayer and Phelps have made to my design. No originality is claimed for it as I have since found that similar calculators are already in

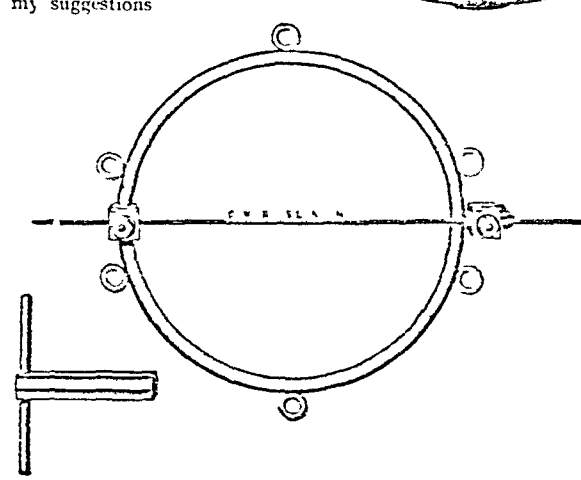
existence, notably one distributed to the profession by a well known firm of infant food manufacturers. The gestation period calculator gives the expected date of delivery with the same accuracy as the ordinary obstetric tables already referred to, but—and this is the important point—it also gives the period of gestation in weeks on any required date or conversely the date on which any period of gestation will be reached. This information so readily available must lead to a saving of time by eliminating tedious calculations and to greater accuracy in describing the progress of pregnancy by encouraging those engaged in ante-natal work to refer to the period of pregnancy in weeks instead of in months as is the more common custom at present. The calculator works like a slide rule and consists of two scales, one engraved on an outer fixed rim, the other on an inner revolving dial. The outer scale has 365 divisions representing days in the year, the months and every fifth day being clearly indicated. The inner scale has forty divisions representing weeks, each division being equal to seven of the small divisions on the outer scale. There are only forty divisions on the inner scale because the usual duration of pregnancy is forty weeks. At zero on the inner scale is an arrow marked "First day of last period" and opposite twenty-eight and forty weeks respectively are printed "Viability" and "Full Term." To use the calculator it is only necessary to rotate the dial until the arrow points to the date on the outer scale corresponding to the first day of the last menstrual period and then to compare the two scales. It will now be possible to read off the date of expected delivery, the date when the child will be viable, and the period of gestation in weeks on the date of examination or on any other date. As illustrated the calculator is small and compact and can be easily carried in a waistcoat pocket, but it is possible to have a larger model suitable for hanging on the walls of ante-natal clinics. One hesitates to add further to the mechanical devices with which obstetrics is already burdened, but I feel that the one just described will supply a real want and be useful to all those engaged in obstetric practice, whether they be specialists, general practitioners or nurses.

NEW APPARATUS FOR WIRE EXTENSION

Mr. H. S. SOUTTAR, F.R.C.S. (London, W.) writes:



The wire extension method of Kirschner is generally admitted to be far superior to all other methods of applying extension to the long bones. It has however suffered from the defects that the apparatus required was cumbersome and expensive. The devices I am about to describe are simple, effective and inexpensive.



For the support of the wire during its insertion a telescope arrangement of three tubes is provided and this can be attached to either a hand or motor drill. Supported by these attachments the finest piano wire can be drilled through any bone in a straight line.

A circular steel ring of suitable size is slipped over the limb and the wire is attached to it by two small clamps so that it lies across a diameter of the ring. One of these clamps can be moved outwards by a small screw so as to place on the wire any tension that may be required. The bone is thus supported on a wire stretched tightly across the diameter of a substantial steel ring.

The ring itself is so arranged that it can be slung from any form of Balkan beam, whilst extension cords may be attached to the ring at the ends of the wire. Fragments of bone are thus completely controlled by the ring and may be rotated or extended as may be required.

The whole apparatus is readily sterilized, is extremely simple to manipulate and is quite inexpensive. I am most grateful to Messrs. Down Bros. for the care with which they have carried out my suggestions.

ETHICS OF ABORTION, STERILIZATION, AND BIRTH CONTROL

ADDRESS BY LORD RIDDELL

At the opening of the second winter session of the Hampstead General and North West London Hospital Post Graduate School on January 6th an address was delivered by Lord RIDDELL, who took as his subject "The ethics of abortion, sterilization, and birth control."

Lord Riddell said that the much discussed subject of abortion raised questions of supreme difficulty. The practice was one which few of the ancients before the Christian era seriously condemned. Certain Greek philosophers, notably Plato and Aristotle, expressed themselves directly in its favour. Abortion was not expressly prohibited by the Mosaic law and the New Testament was silent on the subject. The Christian Fathers declared that "one identical life principle exists from conception to death" and that consequently abortion at any stage was murder. That was still the Roman Catholic view. The Jews on the contrary regarded abortion as justifiable when performed to protect the mother.

THE LAW AND ABORTION

In England abortion had been a crime for some 600 years but the first statutes prohibiting it were not passed until the early nineteenth century. The existing law was comprised in the Offences Against the Person Act 1861, which provided that any person who unlawfully used any instrument or drug with the intent to procure a miscarriage should be guilty of a felony. It was agreed by lawyers and doctors that a miscarriage might be lawfully procured when the object was to save the mother's life or to avoid serious injury to her health; the essence of offence was guilty intent. Lord Riddell went on to refer to the startling criticisms of the administration of the law recently made by Mr Justice McCardie. There was no doubt that the learned judge had performed a public service in directing attention to the subject, but he had created a most difficult situation for if a prisoner came before Mr Justice McCardie or some other judge who shared his views he might expect lenient treatment if it could be shown that the abortioner was trying to help a woman in distress; on the other hand if the case was tried before a judge with more conventional views a drastic sentence might be expected. Abortioners of course, usually plied their trade for money not to relieve distress. To the average mind there was a vast difference of opinion between abortion at an early stage in the development of the foetus and at a later stage, and the early statutes of 1802 and 1828 drew a distinction between a woman quick with child (quickening being supposed to occur about the eighteenth week) and one not quick. It seemed highly desirable that the law should be altered, or that there should be an agreement between the judges as to the principle on which these cases were dealt with. Parliament was not likely to change the law without strong pressure from public opinion.

This was largely a woman's question, and in Germany where abortion was more prevalent than in any other country the subject had been actively taken up by women. There was ample evidence that failure to reduce maternal mortality was largely due to the influence of abortion and attempted abortion. An early solution could not be hoped for as the subject was tangled up with tradition, religion, sentiment, false modesty and the like. It could only be hoped that temperate discussion would enable a way to be found out of the difficulty.

CONTRACEPTION

Turning to birth control Lord Riddell traced this movement back to the doctrines of Francis Place in 1822. Certain sections of the community—Roman Catholics and numerous members of other religious bodies—were bitterly opposed to contraception and there was a certain amount of criticism based on hygienic reasons. The official view of the Church of England was set forth in the resolution of the Lambeth Conference of 1930, which laid stress on abstinence while admitting that there did exist moral situations which might make it obligatory to use other methods. "Each couple must decide for themselves as in the sight of God after the most careful and conscientious thought and if perplexed in mind after taking competent advice both medical and spiritual." The exponents of birth control held that there was no divine or human law prohibiting this practice that practised in moderation it exercised a hygienic moralistic influence, inasmuch as it facilitated marriage prevented the ruin of women's health by too frequent pregnancies, enabled parents to moderate their families in proportion to their means and thus to maintain and educate their children in comfort. In short, the birth control party claimed with much vehemence that the subject should be dealt with on purely utilitarian principles. After pointing out the dilemma in which these controversies placed the ordinary man or woman and noting one helpful passage in the recent Encyclical of the Pope in which it was admitted that in matrimony as well as in the use of matrimonial rights there were secondary ends, Lord Riddell said that perhaps the answer would be best provided by the verdict of the majority and the birth rate figures in all European countries and in America showed the views of the majority in unmistakable fashion.

STERILIZATION OF THE UNFIT

Turning to the subject of sterilization Lord Riddell said that it was generally agreed that lunacy and mental deficiency were serious menaces to the national well being, also that these were largely hereditary diseases. The segregation of mental deficients was incomplete as the patients were usually allowed out on parole for short periods. Social reformers alleged that voluntary sterilization surrounded by numerous precautions would go far to prevent the propagation of more mental defectives, also that much needed economies might be effected and the lives of many of these unfortunate people be made happier as they would be able to reside with their relatives. The objection to the proposal was threefold. The religious objection as in the case of abortion did not lend itself to argument. Another objection was on the ground that it would infringe individual freedom but to this it was replied that the operation would only be performed with the consent of the patient or of his or her relatives and that the sanction of an independent judicial body would also be required. There was a third a sentimental objection which might be expressed in the words of the Bishop of Exeter when dealing with birth control. If life has been sweet to us why should we deprive others of the privilege we value and enjoy? The exponents of birth control however characterized the sentimental objection as absurd.

It was easy said Lord Riddell in conclusion to appreciate the arguments against abortion and birth control among the normal but from a logical ethical and economic point of view it seemed to him that the arguments of those who demanded sterilization of the mental defective were unanswerable.

The ninth conference of the International Federation of Eugenic Organizations was held at Farnham, Dorset, in September 1930 and a report of the proceedings has now been published in pamphlet form. Copies may be obtained from the honorary administrative secretary, Mrs C. B. S. Hodson, 406 Fulham Road, S.W.6. The contents include a note on blood group researches in Holland by Dr Van Herwerden, a report by Mrs Bosanquet on American research on mental measurement, papers on hemilateral asymmetry by Mr C. J. Bond, on inherited variability in corneal size and refractive index by Dr P. J. Waardenburg, and on heredity of eye colour by Dr G. P. Frets, and Sir Arthur Keith's address on the urgency of eugenic reform.

British Medical Journal

SATURDAY, JANUARY 16th 1932

THE AURAL COMPLICATIONS OF INFLUENZA

The paper read at Eastbourne by Mr J. T. O'Malley and published in this issue of the *British Medical Journal* draws attention to some interesting features of the otitis media which is likely to attack many sufferers during the present epidemic of influenza. It has been a general rule during past epidemics that in the early weeks otitis media is mild and relatively infrequent, becoming more severe and more frequent towards the end of the winter and the beginning of the spring. As recent years have provided experience of which the significance is not always appreciated it is appropriate to take stock of the position to-day. The removal of adenoids and tonsils, doubtless responsible in part for the much diminished incidence of chronic otorrhœa, has not proved so effective a prophylactic against this form of acute otitis as was expected, and it seems as though sometimes in young children the removal of lymphoid tissue has actually impaired the defensive mechanism of the individual. The statistics of Dr. Albert Kaiser[1] obtained from two groups of 2,200 children (noticed in our issue of November 1st, 1930, p. 743) are convincing. He shows that for the first three years after operation the average incidence of otitis media is reduced, though over a period of ten years it is not much influenced, but from the standpoint of the individual this is probably of minor importance.

The influenzal type of otitis media has often a sudden onset and rapid course, so that if paracentesis of the membrana tympani is to be of benefit in arresting spread of the infection and damage to the tympanum it must be performed early, before the intratympanic pressure has risen very much. Mr. O'Malley in the paper appearing at page 90 protests against the indiscriminate performance of this operation—a conservative attitude which must receive general approval. On the other hand, too rigid an adherence to the principles which he lays down would in many cases allow the favourable moment to pass. This difficulty however can be surmounted by repeated examination of the patient at intervals of a few hours. An increasing congestion in the postero-superior quadrant of the membrana tympani, even without persistent pain, calls for paracentesis. The delay in its performance until the whole membrane is bulging has been responsible for much of the discredit brought upon the operation by many cases in the past when it has failed to prevent the need for a mastoid operation later on. Mr. O'Malley discusses the subsequent infection of the mastoid process as either streptococcal or pneumococcal, but aural surgeons are aware from their own experience that when mastoid complications arise they fall into two groups which have been lucidly described and differentiated by Kopetzky—the coalescent mastoiditis in which the bony framework of the mastoid cells is gradually destroyed, and the acute haemorrhagic mastoiditis associated with infection by the haemolytic streptococcus. In the first variety operation should be delayed for several days because resolution occurs in some cases, and after an interval the operation is performed with greater safety from further complications when a local immunity has been established. The haemorrhagic variety calls for operation as soon as the diagnosis is certain.

The introduction of bipp by Rutherford Morison made possible the suture of many infected wounds with primary union, the conditions being adequate excision of damaged tissue and the obliteration of all dead spaces beneath the line of sutures. The world-wide influenza epidemic at the end of 1918 provided a large number of cases of acute mastoid disease in which this method was applied, but although primary union may apparently be obtained in the course of a few days a dead space is often left enclosed by the rigid walls of the mastoid process. The late result of this form of surgery has been that a subsequent attack of otitis media causes the formation of an abscess in the dead space, and the patient presents himself usually at another hospital with the post-aural scar bulging from a collection of pus beneath, whilst a row of stitch marks on either side tells clearly the history of the case. On reopening the wound a cavity is found with ragged overhanging edges and filled with pus and soft granulation tissue. This short cut to healing as applied to the mastoid process has not, in the long run, proved a success, and where the cavity left by the operation is large it is best kept wide open to granulate or at any rate only partially sutured. The cases suitable for primary suture are those in which the knee of the lateral sinus projects far forward close up to the posterior meatal wall, and where (as is usually the case) the middle fossa is low. In such circumstances even if an extradural abscess has formed the cavity may be obliterated by blood clot which soon forms fibrous tissue, according to the method proposed many years ago by Blake and Reik. This process may be assisted by turning a slip of pericranium into the cavity.

The lesson to be learnt from the foregoing considerations may be summed up in a few sentences. Paracentesis is required early, before the pressure rises much in the tympanum, and its unnecessary performance may be avoided by repeated examinations at short intervals. If a mastoid operation appears necessary the surgeon should determine to which group the case belongs before deciding when to operate. In the majority of cases the post-aural wound should be left wide open.

[illegible] Surg., London, 1931.

[illegible] *Diseases of the Ear*, 252, London, 1931.

The Carrel-Dakin method of dressing is generally more suitable, and gives a firmer scar than the method of primary suture, although the convalescence is longer There is one more point At this season it is not rare for an old otitis media, of which the patient was unaware, to be wakened into activity, and the misleading history may give rise to a serious mistake in the management of the case

OVULATION AND THE SEX CYCLE

In a communication shortly to be published in the University of California Memoir Series (of which we have received an abstract), Professor Herbert M Evans, who is well known for his work on the hormones of the pituitary, in co-operation with Dr Olive Swezy, puts forward a number of results which appear to throw new light on the biology of the reproductive cells of the ovary [1] The authors have investigated the genesis and growth of ova in a number of mammalia, and the relation of this process to the normal sex cycle of the animals They have found that ovogenesis occurs throughout the whole of sexual life in a rhythm fundamentally related to the ovulation cycle The ova arise by proliferations from the germinal epithelium in the form of invaginations or cords forming groups of epithelial cells which are cut off from the epithelium and pass through the tunica albuginea Follicles are formed and grow rapidly, until one or more of them ovulate A striking phenomenon is then witnessed, for the final maturity and ovulation of a selected group of follicles or of a single follicle involves the destruction of all remaining follicles This occurs, to some extent, at all periods of the sex cycle but reaches its maximum at anoestrus or pro-oestrus, extending into the next cycle Even during pregnancy the rhythm of the follicular cycle is not obliterated Thus the old concept that in mammalia the ova are all formed before birth and remain quiescent until sexual maturity appears to be no longer tenable On the contrary it is shown that the ova of adult life are being constantly produced and just as constantly destroyed

The question whether the follicular cycle and ovulation bear any temporal relation to the period of ovarian hormone secretion is of great importance and has been studied by the authors It has been found that in the rat guinea-pig and dog the follicular cycle normally coincides with the oestrous cycle Ovulation then, presumably occurs during the period of secretion of the α-hormone (oestrin) by the ovary In man the conditions are to a great extent different ovulation seems to occur at approximate intervals of twenty-eight days But both in the human subject and in the monkey the follicular cycle has no necessary relation to menstruation and ovulation takes place at any time during the menstrual cycle This question of the time of ovulation in primates has been the object of a good deal of controversy it is intimately connected with our conception of the mechanism responsible for menstruation and the relation of the latter to pregnancy Recent work has led to a new point of view concerning the significance of the menstrual phenomenon It seems to indicate that the corpus luteum is responsible for the proliferation of the endometrium of the uterus in the period preceding menstruation What part the α-hormone (oestrin) plays in this proliferation in the human subject remains at present, undetermined although it is significant that as Zondek has recently shown the urine content of gonadotropic hormone (follicular maturation hormone) rises during the intermenstrual period, and is highest during the premenstrual period If conception takes place then the activity of the corpus luteum continues and menstruation of course does not occur In the absence of conception, however, the luteal secretion ceases The proliferated uterine endometrium is then no longer subject to the action of luteal hormone, and consequently degenerates This degeneration of the proliferated endometrium constitutes the process of menstruation

The point of view outlined above is strongly supported by the work emanating from the Graz Clinic, where a method for determining the period of activity of the corpus luteum has recently been elaborated Working in the first instance on the rabbit Professor Knaus showed that the uterus of pregnant and pseudo pregnant animals give no response to pituitrin, and that the hormone of the corpus luteum was actually responsible for this inhibition of the normal uterine reactivity [3] These findings have been confirmed and amplified by a number of observers The reactions of the normal human uterus to the active principle of the posterior lobe at various stages of the menstrual cycle, were then determined It was found that in the early stages of the post-menstrual period the intravenous injection of pituitrin caused contraction of the uterus, in the later stages (after about the sixteenth day) pituitrin had no such effect The absence of the uterine reactivity prevailed until the end of the intermenstrual period, then pituitrin again caused contraction These experiments which have been confirmed by a number of observers, have led to the conclusion that the corpus luteum exercises its secretory activity from the sixteenth day to the end of the intermenstrual period, and, consequently that ovulation occurs some time between the fourteenth and sixteenth day after the *beginning* of menstruation (this only applies to a menstrual cycle of twenty-eight days) If this is actually the case then conception can only occur for a limited period of time (at the most probably from the eleventh to the seventeenth day of the menstrual cycle) A number of clinical experiments recently published by Knaus appear to confirm this point of view [4]

That ovulation should occur independently of ovarian hormone secretion seems to be quite possible, and would find support in the hypothesis recently advanced by Leonard on the basis of his experimental findings, that

[4] Knaus *Munch med Woch* 1931 ix 344

the ovulation principle of the pituitary is different from the follicular maturation and luteinizing hormones[1] Ovulation is however followed by formation of the corpus luteum One line of evidence reviewed above strongly suggests that ovulation occurs at a definite stage in the menstrual cycle and is followed by a period of luteal activity It is, as yet, too early to arrive at a definite conclusion on this matter but the data so far available make it highly desirable that further inquiry should be undertaken in this subject

STANDARDIZATION OF ERGOT

The subcommittee on ergot appointed by the Pharmacopoeia Commission has now issued a report The biological method of standardization developed by Broom and Clark was based on the power of ergotoxin to inhibit the motor response produced by adrenaline in the isolated uterus of the rabbit This estimated the ergotoxin content of ergot but unfortunately it was difficult to carry out with accuracy After making an extensive series of comparative tests in different laboratories the subcommittee concluded that the error was unlikely to be less than 25 per cent and might be very much greater It next examined a variety of colorimetric tests and found that one described in 1930 by Dr M I Smith gave results in fair concordance with those obtained by the biological method Further research showed that this test was not strictly specific because it estimated not only the therapeutically active alkaloid ergotoxin but also the biologically inert alkaloid ergotinine which constitutes from 25 to 50 per cent of the total alkaloid content of ergot The subcommittee was faced with the choice between two methods of standardization the biological which was laborious inaccurate but specific and the chemical which whilst far simpler was not specific Deciding that in practice the chance of error with the two methods was approximately equal it chose the easier chemical method The ergot preparations in the current *Pharmacopoeia* are unstandardized moreover by an unfortunate accident the method prescribed for the preparation of the liquid extract results in a product which is therapeutically inert The introduction of any method of standardization will therefore represent a very great advance on past practice It is to be hoped that the introduction of active pharmacopoeial preparations of ergot will result in the rescue of this useful drug from the somewhat undeserved neglect into which the prevalence of inert preparations has thrown it but at the same time it should be remembered by clinicians that active ergot preparations are powerful drugs with a well marked cumulative action The subcommittee recommends that the strength of the liquid extract should correspond to 0·03 per cent of ergotoxin A higher strength than this (0·05 per cent) was first considered but it was believed that this might prove dangerous A further recommendation is that powdered dusted ergot be recognized by the *Pharmacopoeia* This is a useful innovation for it has been shown that such a preparation is reasonably stable whereas the liquid preparations of ergot deteriorate fairly rapidly on storage

RETINOSCOPY

Few who practise ophthalmology can realize the contrast between the assurance given by modern methods of examining refraction and that of a decade by the old subjective tests Retinoscopy was unknown until 1873 when Dr Cuignet of Lille published his first paper on keratoscopy in the *Recueil d'Ophtalmologie* It is true that fourteen years earlier Sir William Bowman had to all intents and purposes discovered the method of examination of the refraction in certain ocular conditions for in his paper on conical cornea in *Ophthalmic Hospital Reports* for 1859–60 he wrote

> Soon after the immortal invention of Helmholtz I found the ophthalmoscope very useful in detecting high degrees of conical cornea For this purpose the concave mirror is to be used without a convex lens On turning the mirror so as to throw the light at different angles the side of the cone opposite to the light is darkened Probably everyone is now familiar with this test Professor Donders told me last year that he himself observed it It is a very useful one in discriminating the cases of slight defects of vision somewhat resembling myopia and hitherto deemed anomalous I have seen many such cases

No one thought of trying to vary the effect of this reflex until Cuignet put lenses before the eye under examination and found that he could modify the reflex at will, and thereby determine the focus of the eye But his knowledge of optics was so poor that his description of the phenomena he observed was almost unintelligible and the value of the method was undetermined until Parent of Paris had the curiosity to go to see what the bother was all about Since then many have written books long and short on this method of examination of the eye and described variations of mirrors and lens equipment The latest of the kind is a little work by Dr Margaret Dobson[1] It is curious that even to-day the errors of the original discoverer should still be perpetrated Dr Dobson continues to write of the "shadow test" It is true that this test was first discovered because of the curious dark shadow seen in gross error of refraction but for the vast majority of cases the essential visible feature is the light shining out of the eye Many have maintained that it should be properly described in positive terms—namely in terms of light as the "light test" Landolt insisted upon this The point is practical and not merely pedantic if the student is taught to look for the light he is more certain to appreciate the meaning of the phenomena and as a consequence master the method more readily Dr Dobson gives a general description of some of the reactions of retinoscopy and follows this with an account of muscular imbalance accommodation and convergence The epithet dynamic seems rather fantastic as applied to so old a branch of investigation but it is copied from a paper by the Dr A Y Cross of New York who directs the retinoscope while the patient was looking and concentrates the eyes upon the point at which the surgeon was working so that some objective measure of the ophthalmic accommodation and convergence might be obtained The method has some limited value

THE TRAFFIC IN NARCOTIC DRUGS

At the last meeting of the Permanent Central Opium Board of the League of Nations it was noted that although the Geneva Convention had received a larger number of ratifications than any other of the League's numerous conventions, many of the Latin American countries failed to supply the required statistics that Turkey and China had furnished no figures in regard to the production and export of raw opium, and that the French Government had been dilatory in the dispatch of statistics in respect of its colonies It was also noted that the consumption of coca leaf was higher in 1930 in France than in any other country In the course of the conference on opium smoking at Bangkok the United States Government has through its representative, declared emphatically against Governmental monopoly in opium holding that the use of opium for other than medical and scientific purposes should be *regarded as illegitimate* *It continues to press for the* early suppression of opium smoking, as contemplated by Chapter 2 of the Hague Convention of 1912, and concurs in the view that the limitation and control of poppy cultivation are eminently desirable At the last Assembly of the League a resolution was adopted requesting the Advisory Committee on the Traffic in Opium and other Dangerous Drugs, and the secretariat of the League, to collect material which would serve as a basis of discussion at a future conference on the limitation of the production of opium, and the cultivation and harvesting of the coca leaf

---

THE CANCER CAMPAIGN

At the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held on January 11th with Sir John Bland-Sutton in the chair, Mr C H Fagge was elected a member The following grants were approved £3 000 to the Middlesex Hospital towards the maintenance of its cancer research work for six months, £1 500 to the Cancer Hospital for research work for six months £150 to Dr Thomas Lumsden in connexion with his serum work at the London Hospital £75 to Miss Goulston B Sc, and £17 10s to Dr H P Bayon of Cambridge A report was received from the joint committee of representatives of the Campaign and the Mount Vernon Hospital, nominating Dr A E Barclay lecturer in medical radiology and electrology at the University of Cambridge, to the radiological research fellowship founded by Sir William Morris, at the Mount Vernon Hospital The Council was informed that Dr Barclay hoped to begin his new duties as soon as he can complete the present work connected with his examinerships A memorandum from the National Radium Commission was submitted to the Council wherein the Commissioners expressed a desire for the co operation of the British Empire Cancer Campaign in helping forward a policy of confining radium treatment only to those radium centres in provincial hospitals which have been selected and approved by the Commission It was reported that a recent questionary drawn up by the Central Bureau of Hospital Information on behalf of the Campaign showed that there are three principal groups dealing with radium at the present time King Edward VII Hospital Fund administering radium to the hospitals within the London area, the National Radium Commission, administering radium outside the metropolitan area, and an independent group of over one hundred centres, established in hospitals of fifty beds and upwards in England Scotland, and Wales controlling approximately 16 8 grams Apart from these three groups there is also a considerable quantity of radium owned privately by surgeons The Council resolved to co operate as far as practicable in helping the National Radium Fund with the policy of radium distribution, so that every part of the country shall be adequately served, and that the use of radium for therapeutic purposes shall be in the hands only of those well qualified to use it

---

NEW CONQUESTS FOR PHYSICS

The realm covered by physics and optics is continually extending and the annual exhibition of the Physical and Optical Societies—*the twenty second of which has* just been held at the Imperial College of Science—affords a means of measuring this steady conquest The exhibition is divided into two principal sections one dealing with the products of commercial firms in the way of scientific apparatus, and the other with researches and experiments carried out in national laboratories But there is no clear line of demarcation, and it is evident that much useful research is being conducted under commercial auspices Every year the scientific apparatus gathered together at South Kensington appears more ambitious in the facilities it offers for the measurement and even the control of natural phenomena It is interesting also to trace in complicated apparatus the long descent from some simple contrivance serving a domestic use The alarm clock, for example might itself feel alarmed on beholding its prodigious offspring in the form of a programme clock—a clock which carries through a predetermined programme for the day, ringing bells, sounding hooters switching furnaces on and off and maintaining the routine of processes in the factory Another marvel is the multi-recorder, whose moving finger records the actual time of occurrence or duration of events, the time of opening and shutting of valves, switches, gates, or doors, the duration of machine operations, the time of burning fuses, of the flight of shells, of the operation of the automatic telephone not to mention physiological reaction times Then photo electric spectrophotometers for measuring easily and quickly the ozone in the upper layers of the earth's atmosphere were exhibited together with many precision thermometers and humidity indicators and instruments connected in one way or another with meteorological science An artificial ear was another wonder, used by the Post Office for testing telephone receivers, and having exactly the same reactance and resistance as the human organ of hearing Then there was a host of optical devices new lenses and microscopes and an epidiascope embodying a new system of illumination and ventilation, enabling the most delicate and valuable specimens to be shown without fear of damage by heat On the physiological side some photographic records by Professor A V Hill of heat production in muscle twitch and during nerve stimulation were of interest Professor E W Scripture of Vienna again showed some apparatus for the study of speech, and curves obtained

in recording spoken vowels and consonants and in an exhibit from the speech laboratory of the West End Hospital for Nervous Diseases the typical curves for the articulation of the normal person were compared with those indicative of the laryngeal ataxia associated with disseminated sclerosis and cerebellar lesions The record of the sound *ah* in the normal person for example consists of a series of regular waves but in a patient with disseminated sclerosis there are two or three distinctly irregular waves at the beginning or end of the vowel sound Each wave registers a puff from the larynx and the irregular waves illustrate the ataxic action of the laryngeal muscles Many examples were given of the speech form in the epileptic condition which is said to be specific not capable of imitation by the normal person, and to afford an infallible diagnostic test

THE JEWISH HEALTH ORGANIZATION

Few societies in recent years have shown more enterprise and perseverance than the Jewish Health Organization of Great Britain In the short period of seven years the work of the organization in regard to child guidance health education, and medical research has become well known and its value has been recognized by central and local authorities The report for 1929–30 which is issued on behalf of the executive committee by Drs Redcliffe Salaman and A H Levy deserves careful attention because it elucidates with much insight some of the practical issues that confront the social worker in a complex community Among the subjects discussed is the recently instituted dental clinic for adolescents established in November 1930 in order to make adequate provision for juveniles who had left school but were not yet eligible for national insurance benefit The clinic has a permanent clientele and works along with other centres in regular contact with the young Every member is inspected dentally at least once a year and given necessary treatment and advice Educational propaganda emphasizing the importance of periodical examinations and early preventive treatment is conducted at the time of the inspection and talks on oral hygiene are arranged at clubs and similar institutions The scheme provides that patients must contribute towards the cost of their treatment and that only necessitous cases shall benefit Provisionally the affiliation fee charged to each member is is a year payable through the institution to which he belongs with a minimum of £2 a year per institution To facilitate concentration on conservative treatment and to save time for educational and minor dental work members joining at the earlier ages after leaving school receive precedence thus reducing the amount of operative treatment At present sessions are held at the clinic on two evenings a week after normal working hours The organization feels that the dental clinic has made an auspicious start and hopes in a future report to publish figures which will prove that it is taking a useful place in the health services of the country Progress is also recorded in the work of the Child Guidance Clinic where greater continuity and co-ordination have been effected by the appointment of additional staff From November 1927 to December 1930 the total number of cases seen at the clinic was 200 nearly all the patients being between the ages of 5 and 14 So far the desire expressed in a former report that more children of pre-school age would be sent to the clinic has not been fulfilled and the suggestion is made that this may be due to a misconception of its aims The point about child guidance is to have cases brought to the clinic before parents are likely to consider it worth while consulting a doctor The part therefore which school teachers health visitors and care committee workers can play, by bringing under medical observation difficulties in educational progress, signs of erratic behaviour, or conditions of mental strain and worry is obvious We are convinced from our results that the early cases are the most profitable "

DR. GEORGE H SIMMONS

On January 2nd Dr George Henry Simmons emeritus editor of the *Journal of the American Medical Association* celebrated his eightieth birthday at his home on the sea coast of Florida Dr Simmons was born at Moreton-in-Marsh Gloucestershire and went to the United States at an early age graduating at the General Medical College and Rush Medical College of Chicago He practised for a time in Nebraska and founded the *Western Medical Review* In 1924 on his retirement after twenty-five years as editor and general manager of the *Journal of the American Medical Association* he was entertained at a banquet and presented with his portrait at the annual meeting of that Association when Dr Harvey Cushing Dr William S Thayer and Dr William Mayo expressed the appreciation of all their colleagues for the outstanding services rendered by Dr Simmons to medical literature to medical education to medical organization to science and to the general public welfare An account of the proceedings with a reproduction of the portrait appeared in our issue of September 13th 1924 (p 481) During the past seven years Dr Simmons has spent much of his time in travel and has often visited this country, renewing old friendships We look forward to seeing him at the centenary celebrations of the British Medical Association next summer

The vacancy among the Crown nominees on the General Medical Council caused by Sir Edward Hilton Young's appointment as Minister of Health is now filled by Mr Douglas Hewitt Hacking M P who has held a number of Ministerial posts during the past ten years and was chairman of the Home Office committee on compensation for silicosis

The Hunterian Oration before the Royal College of Surgeons of England will be given by Mr Wilfred Trotter F R S on Monday February 15th at 4 o'clock

Dr C Killick Millard's presidential address to the Society of Medical Officers of Health entitled A plea for the legalization of voluntary euthanasia under certain conditions has now been published in pamphlet form (The C W Daniel Company 2 net) with some additional matter including the text of a proposed Bill and expressions of opinion from medical men and others A report of the address appeared in these columns on October 24th 1931 (p 754)

NEW LIGHT ON WORKMEN'S COMPENSATION

THE GERMAN CODE

Wide and far reaching as the German Federal Insurance Code of 1911 was it failed to place occupational diseases on the same footing as accidents The reason for this seeming anomaly was that most cases of poisoning recovered within the twenty six weeks during which they came under the sickness insurance law entitling them to sick pay and medical and surgical treatment[1] After the lapse of that time, however practically no further relief was obtainable in cases of poisoning or disease involving incapacity partial or total nor in the case of death was any sum recoverable by the dependants Power, however, was conceded to rectify this A beginning was made in 1925 and with additions in 1929 twenty two industrial diseases forms of poisoning and injuries have now been selected for compensation on the same lines as accidents just as thirty three are scheduled under the Workmen's Compensation Act in Great Britain

SCHEDULED DISEASES AND FORMS OF POISONING RECENTLY BROUGHT UNDER THE GERMAN FEDERAL INSURANCE CODE*

Number of Cases Reported and Number Compensated in 1929

	Industrial Disease	Number of Reported Cases	Cases Compensated for the First Time		
			Number	Total Cases Compensated	Reported Cases
				Per cent	Per cent
	Poisoning due to				
1	Lead and its compounds	3 456	421	21 38	12 18
2	Phosphorus	3	—	—	—
3	Mercury and its compounds	91	10	0.51	10 99

* The table is taken from the *Amtliche Nachrichten fur Reichsversicherung* 1930 Heft No 12 For much information the writer is indebted to the article Die Versicherung der Berufskrankheiten in Deutschland by Dr Ludwig Teleky in *Le Assicurazioni Sociali* No 3 May–June 1930

† Including nitro- and amido derivatives of the aromatic series

[1] This explains the discrepancy in the table between the number reported and the much smaller number receiving compensation for the first time on account of incapacity lasting more than twenty six weeks.

A COMPARISON WITH GREAT BRITAIN

The method of investigation and report by specially appointed surgeons is very much the same in Great Britain and Germany but a comparison of their respective schedules of industrial diseases reveals some interesting resemblances and differences Fourteen diseases are common to both of the thirteen or fourteen in the British list not found in the German at least twelve are excluded for the fairly obvious reasons that they are either very rare or are normally curable within the twenty six weeks allowed under the sickness insurance law The conspicuous omission from the German list of miners nystagmus, however is only explicable on the score of the probable expense that would be incurred by scheduling it since in Great Britain the cost of compensation comes to about £1 000 000 yearly The German Government may also have been influenced by fears as to the inclusion of a malady into which a psychological factor enters so largely An effort ought however to have been made at any rate to schedule total incapacity from this cause

The narrowness of the terms under which chronic eczematous conditions (excluding even so common a cause as chrome eczema) are scheduled in Germany is in striking contrast to the wide comprehensiveness of our dermatitis and ulceration of the skin produced by dust and liquids Similarly the limitation in the classes of industry to which severe disease of the lung due to dust (silicosis or tuberculosis accompanying silicosis) applies makes it much less comprehensive than the most recent Silicosis Schemes (1931) in this country The very large number reported in Germany in the first year (14 482) represents an accumulation of cases, in view of the slow development of this malady the German Government wisely permitted claims to be lodged in respect of a period dating back to 1920 Moreover I am informed that the figure includes a large number of cases of miners suffering from any lung condition attributable to dust of which 80 to 90 per cent had nothing to do with silicosis This accounts for the comparatively small number—1 209—awarded compensation

Of the seven in the German list not included in ours—sulphuretted hydrogen poisoning carbon monoxide poisoning lung disease due to basic slag effects from pneumatic tools boilermakers deafness tropical diseases among sailors and infectious diseases among nurses and laboratory assistants—six stand out as having particular interest Cases of carbon monoxide and sulphuretted hydrogen poisoning generally develop suddenly and can be traced to a particular moment They are accidents and compensation should be obtained for them as such this is the principal reason why these forms of poisoning do not appear in our list In carbon monoxide poisoning however, serious after effects are occasionally observed—mental impairment, paralysis and liability to succumb to pneumonia—and with the development of the internal combustion engine and the presence of quantities of carbon monoxide in the exhaust gases much is now heard of chronic gastric and cardio vascular trouble among bus drivers bus conductors and others Considering the widespread use of gases developing a high percentage of carbon monoxide (blast furnace gas power gas) the number of cases reported in Germany and still more the number compensated for the first time are surprisingly small

Since the report of the First Committee on Compensation for Industrial Diseases (of which the present Home Secretary was chairman) the development of the viscose process in the manufacture of artificial silk which is entirely dependent for its success on the use of carbon bisulphide has led to much distress among spinners, minute traces of sulphuretted hydrogen setting up an irritation of the eyes Both these forms of poisoning have been referred by the Secretary of State to the Committee on Industrial Diseases now sitting for consideration as additions to the list of scheduled diseases

Out of three hundred and thirty one cases reported in Germany of diseases of the "muscles bones and joints

[2] Flanders dinitrophenol dope poisoning tetrachlorethane nickel carbonyl poisoning by African box wood compressed air illness miners beat hand knee and elbow telegraphists writers, and twisters cramp

from the use of pneumatic drills thirty one were compensated as disabled after the lapse of the twenty six weeks treatment received under the Sickness Insurance Act According to Dr Maria Sevring (*British Medical Journal* 1930 ii 1013) the maladies affecting pneumatic drill workers are angioneurosis of the capillary vessels of the fingers leading to Raynaud's disease atrophy of the muscles of the thenar and hypothenar eminences and interossei supplied by the median radial and ulnar nerves the biceps and infraspinatus and injury to the elbow joints and shoulder joints *Mutatis mutandis* similar conditions are found among the comparatively few men employed on pounding up machines (for removing creases in the leather when the upper is fixed to the insole the machine vibrating 16 000 times to the minute) The German figures make out a case for inquiry into this form of injury not only to ascertain the extent of the disability but also to stimulate engineers to find a means external to the workman for carrying out this process

The Home Office Committee of 1907 heard evidence from Middlesbrough about slag cough and described it as a slight chronic inflammation of the bronchial tubes induced by the extremely fine state of division into which basic slag has to be ground This illness has some distinguishing features and may be held to be specific to the employment but it cannot be included in the schedule for the reason that the evidence shows that it does not incapacitate for more than one or two days" No further evidence in this country has been advanced questioning the correctness of this view which is, however in striking contrast to the experience in Germany both before and since the above opinion was expressed The reason no doubt is that in comparison with Germany the preparation of basic slag in this country is on a very small scale In years past I had been mystified by the number of cases of pneumonia referred to in the German Factory Inspectors Reports from inhalation of basic slag dust Thus a report on basic slag works made by an official of the Imperial Health Office stated that in 1892 in eighteen works 91 1 per cent of the workers became ill 56 4 per cent of the cases were diseases of the respiratory organs and of twenty four deaths nineteen were due to respiratory diseases Again in 1893 in twenty one works sickness amounted to 108 9 per cent 54 5 per cent of the cases were due to respiratory diseases and of twenty two deaths eighteen were due to such diseases As a consequence statutory regulations requiring monthly examination of all persons employed in basic slag works were enacted Improvement by meticulous locally applied exhaust ventilation must have followed as the figures of cases reported thirty six and of those first compensated nine in the table for 1929 are reassuring

Boilermakers deafness is referred to by the 1907 Committee as unquestionably an injury due to employment and as widely prevalent among men working in incessant noise of the shipbuilding yard or the boilermakers shop It does not however prevent a man from continuing at his trade and cannot therefore give rise to claims for compensation on the grounds of incapacitation but may it not lead to inability to secure work on the reopening of yards or shops after a temporary closing down? And here the German list shows one hundred and forty eight referred and fourteen included in the list of the more or less permanently incapacitated Dr Thomas Barr from an examination of one hundred boilermakers and a comparison of their power of hearing with that of a similar number of iron moulders and postmen in Glasgow found that no one engaged in boilermaking for any length of time escapes impairment of hearing and that three fourths of the number could either not hear at all at a public meeting or only with difficulty The deafness is due to atrophy of the sensitive membrane in the cochlea and the organs of Corti which constitute the receiving board of impressions of high pitched notes

Tropical diseases spotted fever and scurvy contracted by sailors is a remarkable exclusion and though the numbers (181 and 1 respectively) are small they show it to have been worth while Seamen are altogether excluded from our code as the machinery set up (a certificate from the certifying surgeon of the district in which the person was employed) is inapplicable

Lastly infectious ailments contracted by nurses laboratory assistants disinfectors and the like stand third and fourth respectively in the German list of cases reported and compensated for the first time The possibility of including such cases was discussed in the 1907 Committee's report It was held that while in individual cases—as for example that of a disinfector contracting small pox—the evidence in favour might be strong, yet neither the wording of the Act nor the character of the Third Schedule in its present form nor the discussion of the Bill in Parliament gives any indication that our legislation on workmen's compensation contemplates cases of ordinary illnesses contracted by chance through exposure to infection while in an employer's service

The boldness therefore of the German Code despite its apparent significant shortcomings justifies my title of New light on workmen's compensation A word—even an apology—may be expected from me as one who signed the 1907 Committee's report the Committee was tied as it thought by the quotation above and the corollary that before a malady could be scheduled it must last more than a week must be gradual in its onset and not an accident and must be so specific to the employment as to enable the disease to be established in individual cases Intimate acquaintance with industrial disease since then makes me think these tenets should be revised and that instead of demanding as essential only some clear cut distinguishable sign more weight should be given to well recognized cumulative effects on workpeople in the occupations

The German figures with the exception of silicosis are likely to increase for some years as knowledge about the maladies becomes more widely disseminated already a steady rise each year has occurred in practically all those diseases which have been scheduled for the four years The increase in the list was deferred so it has been suggested owing to the ignorance of medical practitioners about industrial diseases the truth of this is shown by a decrease year by year in the number of cases marked wrong diagnosis This reproduces the experience of a gradual increase from year to year of not a few of the scheduled diseases in our list with the increasing knowledge of the conditions of compensation gained by workpeople and medical practitioners

ALCOHOL AND MENTAL DEFECT

ADDRESS BY DR NORWOOD EAST

The following is an abstract of a paper read by Dr W Norwood East one of H M Commissioners of Prisons in opening a discussion on on mental defectiveness and alcohol and drug addiction at a meeting of the Society for the Study of Inebriety held on January 12th

The distinction between the mentally defective person and the subnormal inefficient is empirical and mental disorder may become superimposed upon mental defect it has therefore seemed undesirable to restrict the observations to defectives who are certifiable under the Mental Deficiency Acts It has been stated that an increase in the number of mental defectives has taken place during the twenty years preceding 1929 Official statistics show that since 1915 the convictions for drunkenness have greatly decreased and in 1929 (51 966) were less than half the convictions in 1915 (135 811) It appears therefore that the diminution in drunkenness is not reflected in the number of defectives I may be allowed experience in this matter is comparable to that of Norway where it was found many years ago that a great diminution in drunkenness was reported without any decrease in the number of boys

There is little evidence to show that [illegible] as a direct cause of mental defect [illegible] the occurrence of the latter term is used in the present [illegible] It is recognized that the effects of alcohol [illegible]

in young people but they seldom become so addicted to alcohol before reaching the age of 18 years as to produce the arrested or incomplete development of mind referred to in the Mental Deficiency Act, 1927 Nevertheless intoxication in this country is not uncommon in adolescence and in the three months October to December 1925 487 cases of drunkenness in persons under 21 were dealt with by courts of summary jurisdiction in England and Wales and 114 of these were in persons under 18

It is clear from the Report of the Royal Commission on the Care and Control of the Feebleminded the Departmental Committee on the Inebriate Acts and other publications, that the term "mental defectiveness," prior to the Act of 1913 was frequently used in a general sense only From 30 to 70 per cent of the inebriates were said to be mentally defective Recently I found that of 698 persons convicted of various offences during the ten years 1921–30, and certified in prison under the Mental Deficiency Acts 7·4 per cent were, or had been convicted of drunkenness Dr Douglas Turner found at the Royal Eastern Counties Institution less than 2·25 per cent of adult defectives were intemperate Dr Rees Thomas at the Rampton State Institution, found only 3·5 per cent of the defectives could have been called at any time heavy drinkers, and Dr A E Carver approaching the subject as superintendent of an institution for alcoholism and drug addiction found that in 432 adult male inebriates less than 1 per cent were certifiable under the Mental Deficiency Acts The Central Association for Mental Welfare also made inquiries for me of the local associations throughout the country Of twenty-seven areas which sent in replies eighteen were unaware of any cases of alcoholism among the ascertained defectives and in other areas the number was negligible The Central Association itself reported only one case Clearly these results are in marked contrast to the earlier conclusions

The Mental Deficiency Act 1927 extended the conception of mental defect defined in the 1913 Act and some workers consider it extended the use of the term mental defectiveness too far There are others however, who desire to extend the use of the term still further I suggest that to do so would effect a return to the confusion of thought which was apparent before 1913 and also hamper medico-social research

If it is agreed that the association of alcoholism and mental defectiveness is infrequent it becomes a matter of interest to ascertain the reasons Defectives are often seclusive—if not their companions generally are younger than themselves and as impecunious both factors tend to diminish convivial drinking Intemperance is often the result of a complex habit but many defectives, although suggestible lack the powers of attention receptivity retention and association of ideas which enable a particular stimulus to be followed by an elaborate habitual reaction Defectives may be aware of their inferiority and may drink to rid themselves of this disharmony but it is probably true that the outlook of the adult defective towards the community leads him to consider that its units are superior to himself rather than to emphasize his inferiority in regard to them

Defectives live for the most part in the present free from past disappointments unencumbered by imagination and untroubled by the prospect of future hardships They neither censure themselves nor anticipate the disapproval of others The main reason for their sobriety appears to lie in the fact that their personalities are little affected by antagonistic complexes Further the observations of many years on delinquent defectives lead me to believe that as a class they are less homosexual than their fellows although sexual offences are next in frequency to crimes of acquisition If in fact the alcoholist releases repressed homosexual tendencies by his addiction the defective may be seldom an alcohol addict for this reason

Experience of delinquent defectives delinquent inebriates and inebriates who are not delinquents leaves me in no doubt at all that the mental defective as we see him in this country to-day is seldom an alcoholist that if he becomes an addict this is incidental to the mental defect and that the past estimates of the association of alcoholism and mental defect were excessive

The part played by alcohol as a direct cause of entry to the social problem group of subnormals is complicated by the fact that the alcoholist is frequently the subject of other inherent causes of social inefficiency—a psychopathic make-up or asocial or temperamental limitation Only broad suppositions seem justified in our present state of uncertainty concerning the types of case to be included in the group

Prostitutes are a fairly well-defined subgroup of the social problem group and Sanger has shown that 23 per cent of the parents of 2,000 cases were intemperate It is reasonable to assume that many of the daughters were mentally unstable and perhaps their careers were influenced in consequence Alcoholism may be also a direct cause of prostitution but I have no reason to doubt the statements made to me by many prostitutes during eight years' work among this class of prisoner that they were entirely abstemious before they became public women and of others that they were obliged to drink before they had sufficient assurance to accost possible clients

A large number of subnormals lack will-power and force of character, are temperamentally unstable indifferent incompetent and peculiarly liable to solve their conflicts by alcohol A tendency to addiction is also manifest in the cycloid temperament and Kretschmer discussing the schizoid temperament considers its indifference is a common variant of affective insensibility and that from the ranks of the indifferents are recruited the unstable the gamblers drinkers harmless criminals prostitutes tramps and others It is particularly true of this group that in many of its units a vicious circle is easily induced Alcohol restricts their inherent mental limitations and impels them to counteract this by further intoxication It is also true that from among this group are recruited the majority of the alcoholists who appear repeatedly before the criminal courts charged with offences connected with drunkenness, many exhibit both intolerance to the action of alcohol and constitutional imbalance of the instincts and emotions

There seems to be general agreement that it is a difficult matter in our present state of knowledge to assess the importance of alcohol as a direct cause of insanity The general figure given 10 per cent according to some authorities may be less The Alcohol Investigation Committee of the Medical Research Council presented figures which indicate that the changes in the prevalence of alcoholism in women during the years 1913–18 had no observable relation to the number of cases of certifiable insanity The convictions for drunkenness among women showed a continuous fall from 35,765 in 1913 to 7,222 in 1918 but the number of first admissions of women to lunatic asylums showed no such change in 1913 it was 9,372, and in 1918 there was a slight rise to 9,726

Alcoholism is both a symptom and a cause of mental disorder in many patients General paralysis of the insane is a notable exception and many paralytics drink to excess after the disease is declared and before they come under care Alcohol taken in excess also by delusional patients by manic depressives in the exalted or depressed phases of the disorder by epileptics and by demented persons sometimes leads to charges of drunkenness in the criminal courts Although it is perhaps true to say of many insane persons that they are easily affected by alcohol I am inclined to believe that some of the insane and introverted cases which come before the criminal courts show considerable tolerance of the drug

Influence of Drug Addiction

The literature suggests that the estimation of the number of drug addicts is almost impossible to determine with any degree of accuracy in many countries Perhaps mainly because the narcotic is administered in secret its effects may escape public notice and facts are likely to be obscured at least temporarily if a different method of using the same drug comes into vogue and if one drug is replaced by another It is also extremely difficult to ascertain with any degree of precision, the importance of ancestral drug addiction on the mental condition of the offspring Chopra has come to the conclusion that heredity

does not play any part in inducing drug addiction Seleth and Kuh as a result of experience gained in the treatment of 5 000 cases of morphinism state that they have never seen an addict born an addict because his mother was an addict

In this country drug addiction is admittedly infrequent and its influence as a direct cause of mental defectiveness subnormality or insanity for all practical purposes is negligible This appears to be the case also in Egypt India and British Malaya The Indian Hemp Drug Commission as the result of a searching inquiry, considered that only 7 3 per cent of the admissions to mental hospitals in British India were attributable to hashish Chopra was unable to obtain any evidence to show that opium by itself was responsible for mental derangements in India and Samuel at the Central Mental Hospital at Tanjong Rambutan considered that opium as a cause of insanity was negligible

There is however a large body of opinion in America England France Germany, and elsewhere which considers that drug addiction is a sign of an inherent neurotic personality The cases may be divided into two main classes accidental addicts who develop the habit after the drug has been taken medicinally and those forming a larger group who take narcotics because they possess psychopathic personalities In some cases one drug is followed by another or by other extravagances during the course of the disorder

New Zealand

[FROM OUR CORRESPONDENT IN WELLINGTON]

Vital Statistics

For the past year the general death rate was 8 56 per 1 000 mean population which is believed to be the lowest in the world The birth rate was higher than in the previous year but the natural increase was only 1 per cent Diseases of the heart and arteries were responsible for the highest number of deaths approximately one third of the total being due to such diseases Cancer was the next principal cause of death The number of deaths from tuberculosis continued to decrease New Zealand in comparison with other countries having the lowest death rate from this cause While infant mortality had slightly increased the increase was to be found in the number of deaths of infants under 1 month Septicæmia was the chief cause of maternal mortality

Hospital Administration

Mainly as a result of the criticism of Dr Campbell Begg the board of trustees of Wellington Hospital has adopted the principle of decentralizing the administration by appointing four standing committees with subcommittees to attend to matters of detail Each standing committee has a clearly defined sphere of responsibility but the four are co ordinated on a basis that should prevent them from developing into water tight compartments and should promote efficiency and economy If the scheme operates successfully it may be given a wider application and so result in national as well as local economy Apart from the General Purposes Committee and the Fees and Relief Committee there are a Medical Committee and a Nursing Committee The Medical Committee subject to the approval of the board defines the sphere privileges and responsibilities of the different medical and surgical divisions and subdivisions considers reports from their representatives and co ordinates their requirements It considers requisitions for new medical and surgical equipment and arranges staff meetings at which the professional work of the hospital post mortem findings specimens removed at operations and clinical cases presenting difficulties are considered The Medical Committee also advises the board in regard to the standard of nursing service and service given by house surgeons and if requested advises upon the suitability of applicants for medical and surgical appointments In conjunction with the House Committee and the medical superintendent it controls the clinical work of the hospital chiefly with a view to the harmonious co operation of the senior and assistant honorary staff with the stipendiary and nursing staff It is a question whether a detailed constitution such as the foregoing with rules and regulations is to be preferred to reliance on a good understanding as between the sections of the staff of a large hospital but there is no evidence that the two are incompatible and it can be said with truth so far as New Zealand hospitals are concerned that hitherto the honorary staffs have had no proper status and little or no direct contact with the board of management The medical superintendents in the larger hospitals are now to be mainly administrative officers

New Zealand Branch, British Empire Cancer Campaign

Research work is being carried on in the laboratories of the Otago University under Dr Begg and a biochemist has recently been included in the staff The cancer clinics at the larger hospitals are doing excellent work and valuable records are being obtained Radium has been purchased in various instances where necessary and in suitable form and the branch is co operating with the Department of Health to ensure that radium is available only at suitable centres, and its use confined to those who are properly qualified in this branch of radiotherapeutics The response of the people generally to appeals for financial help has been good despite bad times and many other claims and £50 000 is in hand to this has to be added a further sum of £16 500 The intention of the branch is to build up a capital sum of £100 000 as an endowment for the cancer campaign in New Zealand This branch was established at the time of Mr Sampson Handley's visit to this country and has done much already to improve the diagnosis and treatment of cancer cases and to cause the public to take an intelligent but not an alarmist, interest in the campaign against cancer

Scotland

James Mackenzie Institute

The twelfth annual report of the James Mackenzie Institute for Clinical Research St Andrews expresses indebtedness to the Medical Research Council for continuing the grant of £400 towards the upkeep of children's records and also its grant for special research work Expenditure during the year exceeded income by £75 and a strong appeal is therefore made for the raising of an endowment fund if the financial position of the Institute is to be secured and its important work continued During the past year 97 new cases and 1 150 additional notes were added to the files 795 specimens were examined in the bacteriological and chemical laboratories and 472 films were exposed in the radiology department Further progress was made in the inspection and indexing of the records of the Institute At the end of the year 64 5 per cent of the records were found to be complete in that notes had been added in steady sequence 13 per cent needed to be brought up to date and 22 5 per cent were incomplete largely because patients had been lost sight of From a review of 584 records much valuable information was extracted and the committee charged with this duty has been impressed by the abundance of material available in the files of the Institute Its use of the records being now for the most part [illegible] the committee proposes to investigate certain groups of

in young people but they seldom become so addicted to alcohol before reaching the age of 18 years as to produce the arrested or incomplete development of mind referred to in the Mental Deficiency Act 1927 Nevertheless intoxication in this country is not uncommon in adolescence and in the three months October to December 1925 487 cases of drunkenness in persons under 21 were dealt with by courts of summary jurisdiction in England and Wales, and 114 of these were in persons under 18

It is clear from the Report of the Royal Commission on the Care and Control of the Feebleminded, the Departmental Committee on the Inebriate Acts and other publications that the term 'mental defectiveness,' prior to the Act of 1913 was frequently used in a general sense only From 30 to 70 per cent of the inebriates were said to be mentally defective Recently I found that of 698 persons convicted of various offences during the ten years 1921–30 and certified in prison under the Mental Deficiency Acts 7·4 per cent were or had been, convicted of drunkenness Dr Douglas Turner found at the Royal Eastern Counties Institution less than 2·25 per cent of adult defectives were intemperate Dr Rees Thomas at the Rampton State Institution, found only 3·5 per cent of the defectives could have been called at any time heavy drinkers, and Dr A E Carver approaching the subject as superintendent of an institution for alcoholism and drug addiction found that in 432 adult male inebriates less than 1 per cent were certifiable under the Mental Deficiency Acts The Central Association for Mental Welfare also made inquiries for me of the local associations throughout the country Of twenty-seven areas which sent in replies eighteen were unaware of any cases of alcoholism among the ascertained defectives and in other areas the number was negligible The Central Association itself reported only one case Clearly these results are in marked contrast to the earlier conclusions

The Mental Deficiency Act 1927 extended the conception of mental defect defined in the 1913 Act and some workers consider it extended the use of the term mental defectiveness too far There are others however who desire to extend the use of the term still further, I suggest that to do so would effect a return to the confusion of thought which was apparent before 1913, and also hamper medico-social research

If it is agreed that the association of alcoholism and mental defectiveness is infrequent it becomes a matter of interest to ascertain the reasons Defectives are often seclusive—if not their companions generally are younger than themselves and as impecunious both factors tend to diminish convivial drinking Intemperance is often the result of a complex habit but many defectives, although suggestible lack the powers of attention receptivity retention and association of ideas which enable a particular stimulus to be followed by an elaborate habitual reaction Defectives may be aware of their inferiority and may drink to rid themselves of this disharmony but it is probably true that the outlook of the adult defective towards the community leads him to consider that its units are superior to himself rather than to emphasize his inferiority in regard to them

Defectives live for the most part in the present free from past disappointments unencumbered by imagination and untroubled by the prospect of future hardships They neither censure themselves nor anticipate the disapproval of others The main reason for their sobriety appears to lie in the fact that their personalities are little affected by antagonistic complexes Further, the observations of many years on delinquent defectives lead me to believe that as a class they are less homosexual than their fellows although sexual offences are next in frequency to crimes of acquisition If in fact the alcoholist releases repressed homosexual tendencies by his addiction the defective may be seldom an alcohol addict for this reason

Experience of delinquent defectives delinquent inebriates and inebriates who are not delinquents leaves me in no doubt at all that the mental defective as we see him in this country to-day is seldom an alcoholist that if he becomes an addict this is incidental to the mental defect, and that the past estimates of the association of alcoholism and mental defect were excessive

The part played by alcohol as a direct cause of entry to the social problem group of subnormals is complicated by the fact that the alcoholist is frequently the subject of other inherent causes of social inefficiency—a psychopathic make-up or asocial or temperamental limitation Only broad suppositions seem justified in our present state of uncertainty concerning the types of case to be included in the group

Prostitutes are a fairly well-defined subgroup of the social problem group and Sanger has shown that 23 per cent of the parents of 2,000 cases were intemperate It is reasonable to assume that many of the daughters were mentally unstable and perhaps their careers were influenced in consequence Alcoholism may be also a direct cause of prostitution but I have no reason to doubt the statements made to me by many prostitutes, during eight years work among this class of prisoner that they were entirely abstemious before they became public women and of others that they were obliged to drink before they had sufficient assurance to accost possible clients

A large number of subnormals lack will-power and force of character are temperamentally unstable indifferent incompetent and peculiarly liable to solve their conflicts by alcohol A tendency to addiction is also manifest in the cycloid temperament and Kretschmer discussing the schizoid temperament considers its indifference is a common variant of affective insensibility and that from the ranks of the indifferents are recruited the unstable the gamblers drinkers harmless criminals prostitutes tramps and others It is particularly true of this group that in many of its units a vicious circle is easily induced Alcohol restricts their inherent mental limitations and impels them to counteract this by further intoxication It is also true that from among this group are recruited the majority of the alcoholists who appear repeatedly before the criminal courts charged with offences connected with drunkenness many exhibit both intolerance to the action of alcohol and constitutional imbalance of the instincts and emotions

There seems to be general agreement that it is a difficult matter in our present state of knowledge to assess the importance of alcohol as a direct cause of insanity The general figure given, 10 per cent, according to some authorities may be less The Alcohol Investigation Committee of the Medical Research Council presented figures which indicate that the changes in the prevalence of alcoholism in women during the years 1913–18 had no observable relation to the number of cases of certifiable insanity The convictions for drunkenness among women showed a continuous fall from 35 765 in 1913 to 7 222 in 1918 but the number of first admissions of women to lunatic asylums showed no such change, in 1913 it was 9 372 and in 1918 there was a slight rise to 9 726

Alcoholism is both a symptom and a cause of mental disorder in many patients General paralysis of the insane is a notable exception and many paralytics drink to excess after the disease is declared and before they come under care Alcohol taken in excess also by delusional patients by manic depressives in the exalted or depressed phases of the disorder by epileptics and by demented persons sometimes leads to charges of drunkenness in the criminal courts Although it is perhaps true to say of many insane persons that they are easily affected by alcohol I am inclined to believe that some of the insane and introverted cases which come before the criminal courts show considerable tolerance of the drug

Influence of Drug Addiction

The literature suggests that the estimation of the number of drug addicts is almost impossible to determine with any degree of accuracy in many countries Perhaps mainly because the narcotic is administered in secret its effects may escape public notice and facts are likely to be obscured at least temporarily if a different method of using the same drug comes into vogue and if one drug is replaced by another It is also extremely difficult to ascertain with any degree of precision the importance of ancestral drug addiction on the mental condition of the offspring Chopra has come to the conclusion that heredity

does not play any part in inducing drug addiction Seeleth and Kuh as a result of experience gained in the treatment of 5 000 cases of morphinism state that they have never seen an addict born an addict because his mother was an addict

In this country drug addiction is admittedly infrequent, and its influence as a direct cause of mental defectiveness subnormality or insanity for all practical purposes is negligible This appears to be the case also in Egypt India and British Malaya The Indian Hemp Drug Commission as the result of a searching inquiry considered that only 7 3 per cent of the admissions to mental hospitals in British India were attributable to hashish Chopra was unable to obtain any evidence to show that opium by itself was responsible for mental derangements in India and Samuel at the Central Mental Hospital at Tanjong Rambutan considered that opium as a cause of insanity was negligible

There is however a large body of opinion in America England France Germany and elsewhere which considers that drug addiction is a sign of an inherent neurotic personality The cases may be divided into two main classes accidental addicts who develop the habit after the drug has been taken medicinally and those forming a larger group who take narcotics because they possess psychopathic personalities In some cases one drug is followed by another or by other extravagances during the course of the disorder

New Zealand

[FROM OUR CORRESPONDENT IN WELLINGTON]

Vital Statistics

For the past year the general death rate was 8 56 per 1 000 mean population which is believed to be the lowest in the world The birth rate was higher than in the previous year but the natural increase was only 1 per cent Diseases of the heart and arteries were responsible for the highest number of deaths approximately one third of the total being due to such diseases Cancer was the next principal cause of death The number of deaths from tuberculosis continued to decrease New Zealand in comparison with other countries having the lowest death rate from this cause While infant mortality had slightly increased the increase was to be found in the number of deaths of infants under 1 month Septicæmia was the chief cause of maternal mortality

Hospital Administration

Mainly as a result of the criticism of Dr Campbell Begg the board of trustees of Wellington Hospital has adopted the principle of decentralizing the administration by appointing four standing committees with subcommittees to attend to matters of detail Each standing committee has a clearly defined sphere of responsibility but the four are co ordinated on a basis that should prevent them from developing into water tight compartments and should promote efficiency and economy If the scheme operates successfully it may be given a wider application and so result in national as well as local economy Apart from the General Purposes Committee and the Fees and Relief Committee there are a Medical Committee and a Nursing Committee The Medical Committee subject to the approval of the board defines the sphere privileges and responsibilities of the different medical and surgical divisions and subdivisions considers reports from their representatives and co ordinates their requirements It considers requisitions for new medical and surgical equipment and arranges staff meetings at which the professional work of the hospital post mortem findings specimens removed at operations and clinical cases presenting difficulty are considered The Medical Committee also advises the board in regard to the standard of nursing service and service given by house surgeons and if requested advises upon the suitability of applicants for medical and surgical appointments In conjunction with the House Committee and the medical superintendent it controls the clinical work of the hospital chiefly with a view to the harmonious co operation of the senior and assistant honorary staff with the stipendiary and nursing staff It is a question whether a detailed constitution such as the foregoing with rules and regulations is to be preferred to a limited one on a good understanding as between the sections of the staff of a large hospital but there is no evidence that the two are incompatible and it can be said with truth so far as New Zealand hospitals are concerned that hitherto the honorary staffs have had no proper status and little or no direct contact with the board of management The medical superintendents in the larger hospitals are now to be mainly administrative officers

New Zealand Branch, British Empire Cancer Campaign

Research work is being carried on in the laboratories of the Otago University under Dr Begg and a biochemist has recently been included in the staff The cancer clinics at the larger hospitals are doing excellent work and valuable records are being obtained Radium has been purchased in various instances where necessary and in suitable form and the branch is co operating with the Department of Health to ensure that radium is available only at suitable centres and its use confined to those who are properly qualified in this branch of radio therapeutics The response of the people generally to appeals for financial help has been good despite hard times and many other claims and £50 000 is in hand to this has to be added a further sum of £16 500 The intention of the branch is to build up a capital sum of £100 000 as an endowment for the cancer campaign in New Zealand This branch was established at the time of Mr Sampson Handley's visit to this country and has done much already to improve the diagnosis and treatment of cancer cases and to cause the public to take an intelligent but not an alarmist interest in the campaign against cancer

Scotland

James Mackenzie Institute

The twelfth annual report of the James Mackenzie Institute for Clinical Research St Andrews expresses indebtedness to the Medical Research Council for continuing the grant of £400 towards the upkeep of children's records and also its grant for special research work Expenditure during the year exceeded income by £78 and a strong appeal is therefore made for the raising of an endowment fund if the financial position of the Institute is to be secured and its important work continued During the past year 97 new cases and 1 180 clinical notes were added to the files 798 specimens were examined in the bacteriological and chemical laboratories and 472 films were exposed in the radiology department Further progress was made in the respective analyses of the records of the Institute At the end of the year 64 5 per cent of the records were found to be complete in that none had been added in steadily decreasing 13 per cent needed to be brought up to date and 22 5 per cent were incomplete largely because patients had been lost sight of From a review of 884 records nine valuable information was extracted and the committee charged with this duty has been supplied by the Board of Control material available in the files of the Institute It is hoped of the records being now fully prepared the committee proposes to undertake certain [illegible]

cases in furtherance of the principles defined by Sir James Mackenzie in relation to his visceromotor and viscero sensory reflex theory Weekly clinical meetings were held throughout the session, when cases were discussed and views exchanged by the staff The report of work in the children s department states that apart from its value as a means of investigating the primary causes of ill-health the scheme of continuous observation of children is of immediate practical use as it ensures through the co operation of the family doctors, treatment in the earliest stages of illness

Scottish Mental Hospitals

In the annual report for 1930 of the General Board of Control for Scotland it is stated that the average yearly number of mental patients in Scotland is steadily growing, and that the available accommodation is severely taxed At the beginning of 1931, exclusive of patients maintained at home by their natural guardians there were in Scotland 19 241 insane persons of whom the Board had official cognizance These included the inmates of training schools for imbecile children who had not been certified under the Mental Deficiency Act and of the criminal lunatic department of Perth Prison Of these 2 947 were maintained from private sources 16 221 from the rates and 73 at the expense of the State It is evident from the report that the use of restraint and seclusion is diminishing to vanishing point Emphasis is laid on the increasing development of hospital care and nursing and on the greater attention paid to physical rehabilitation and healthful occupation The advantages resulting from the introduction of female nursing of male patients in the hospital wards of mental institutions—a practice which is now almost universal in Scotland—are stressed. Infectious diseases, like tuberculosis and dysentery are now no more prevalent in asylums than in general hospitals The steady increase in the number of persons who enter mental hospitals voluntarily at an early stage of their trouble is referred to in the report and the extension of this practice in the case of rate aided patients is welcomed The number of escapes from Scottish institutions in 1930 was 132 of these patients 54 were brought back within twenty four hours and 98 within a week Accidents numbered 147 which is 7 more than in the previous year 14 ended fatally death in 8 cases being due to suicide Dr George Gibson reporting on the visitation of boarded out patients says that an interesting cause of unrest and one that is a commentary on present day conditions, is that some defectives knowing that their relatives are in receipt of relief are anxious to be 'on the dole themselves A satisfactory report on the feeding of boarded out patients is given by Dr Kate Fraser

Rickets in Glasgow

In view of the gradual disappearance of rickets Dr A K Chalmers s historical survey in the November issue of the *Glasgow Medical Journal* is of much interest particularly since he gives statistical evidence of the [illegible] in the prevalence of this disease and its sequels observed [illegible]gow between 1877 and 1930 It will be recalled [illegible]me to [illegible]9 a report was published in the *British Medical* than the [illegible] of a collective inquiry undertaken by a committee frequency [illegible]ish Medical Association with Sir Isambard Owen alcoholist re[illegible] into the incidence of certain affections addiction the [illegible] for this reason[illegible]sets in the United Kingdom special refer-

Experience [illegible] to Glasgow where the conditions in this [illegible]ebrates and [illegible]ity bad According to Dr Chalmers the [illegible]me in no doubt [illegible]es produced by rickets reached their see him in this [illegible] of intensity and prevalence in Glasgow that if he becomes[illegible]arter of the last century, that for at thereby they have been undergoing amelioration, and that the degree of amelioration may be expressed by the enlargement of the conjugate diameter of the smaller pelves from 2 5 to 3 5 cm Meanwhile the general death rate had fallen from 24 to 15' The hygienic environment of a large part of the Glasgow population gradually deteriorated during the middle third of last century, and was made worse from time to time by recurring periods of trade depression Dr Chalmers shows that systematic resort to osteotomy for lessening the rickety deformities of the lower limbs and to Caesarean section for contracted pelves arose in the generation which was born between 1850 and 1875 The need for these forms of surgical intervention has now remarkably decreased but an interesting contrast is presented as Dr Chalmers remarks, " by the long drawn out character of a movement in disease produced by the conditions which arose during the unregulated growth of a city on the one hand and the sudden acute outbreak which occurred in Vienna as the result of war conditions and grave shortage of food The cause of rickets is now considered to be threefold a lack of certain accessory food factors, an unbalanced mineral content in the dietary, and lack of sunlight In Vienna where the theory of infectivity had found some degree of acceptance, the general increase, during the war of deficiency diseases affecting bony structures was held by some to have confirmed this view The disease came to an end in Vienna at any rate the grosser forms of hunger osteomalacia among adults, with some abruptness in 1920 Dr Chalmers s comparison of the degree of skeletal deformity formerly associated with this disease with the very obvious improvement in recent years is accompanied by reference to changing views on etiology which have been brought about in some measure by the swing over from clinical to laboratory methods of diagnosis

Chalmers's Hospital, Edinburgh

Plans have been adopted for the addition of a new wing and the modernizing of the existing buildings at Chalmers s Hospital Lauriston Place Edinburgh and the hospital will be closed for several months in order that these alterations may be effected The new wing will comprise an operating theatre anæsthetic and x ray rooms and accommodation for the resident medical staff and nurses In the present building the electrical sanitary and heating fittings will be renewed and the total cost of the work will amount to some £13 000

Ireland

Public Health in the Irish Free State

The annual report for the year 1929–30 of the Department of Local Government and Public Health in the Irish Free State comprises details of local finance general administration and the health of the people [1] The death rate for 1929 (14 59 per 1 000) shows a slight increase on that for 1928 (14 17), but it is below that for the preceding decade (14 84) Decreases in mortality were found in cancer tuberculosis, measles enteric scarlet fever and in diseases associated with pregnancy and child birth The highest rates of mortality were registered in Waterford Cork Dublin and Limerick county boroughs, the lowest in Kerry Mayo Galway and Cork counties Of the infectious diseases typhus showed a decline in incidence there being no serious outbreak during the year under review It appears that the disinfestation organized in Kerry in the spring of 1929 has been effective in checking typhus in that county Notifications of

[1] Government Publications Sale Office 5 Nassau Street Dublin (2s 6d net)

diphtheria exceeded those in the preceding year Toxin antitoxin immunization schemes are in operation in areas where diphtheria has been prevalent and it is anticipated that the growing appreciation of the fact of danger from and obvious benefits of the injections will cause an increased number of children to present themselves for treatment at the clinics

There has been a substantial decrease in the maternal death rate which with the figure of 4 10 per 1 000 has now reached the lowest record registered in the country The infant mortality rate is 70 per 1 000 accounted for mainly by broncho pneumonia and pneumonia School medical inspection reveals a high rate of dental caries enlarged tonsils or adenoids and defective vision and a survey extending over two years of 25 000 Dublin children shows the percentage affected with these conditions to have been respectively 50 17 and 12 On the whole the result of the year s examination of school children fails to confirm the alarming views that have been given publicity in respect of the extent of surgical tuberculosis attributable to tuberculous milk School hygiene and sanitation are on the other hand in a backward condition especially in rural districts Light heating ventilation and playground accommodation are often inadequate while in many cases there are dirty floors and windows defective desks and lack of water supply drinking utensils and drying rooms Improvements however are already taking place Progress is also being made in the provision of school meals this is now in force in thirty five districts 167 schools participating The downward trend in the mortality from all forms of tuberculosis has been maintained and during the year 1929 reached the low level of 1 32 per 1 000 Conflicting reports on the efficacy of sanocrysin have been received from tuberculosis officers Approved arrangements for the diagnosis and treatment of venereal disease are now in operation in three county boroughs and twelve counties The supervision of food supplies the mental hospitals housing public assistance and other problems are dealt with in the report

Cost of Public Health Services in Belfast

The Belfast Public Health Committee has given notice that its estimates for the year ending March 31st 1933 will be under consideration at an early meeting The estimated expenditure for the service of the public health department municipal laboratory disinfecting station superannuations port sanitary Purdysburn Fever Hospital meat inspection treatment of venereal diseases and miscellaneous amounts to £57 921 as against an estimated outlay of £59 896 for the year 1931–32 and an actual outlay in 1930–31 of £54 233 The sum of £15 808 is allocated for salaries as compared with £15 750 for the current financial year and in actual expenditure in 1930–31 of £15 813 Fees for analyses are estimated at £1 00 the actual amount spent for a like purpose last year having been £541 £500 is provided for clothing disinfectants and medical notification fees as against an estimated expenditure this year of £1 030 and an actual cost last year of £1 492 The net sum apportioned for the service of the municipal laboratory is £936 as compared with the current year s estimate of £984 while the actual cost last year was £1 040 The disinfecting station will require £1 237 net—£225 less than the estimated net cost for the current financial year Under the heading port sanitary the expenditure for 1932–3 is put at £859 from which has to be deducted £160 leaving a net service of £699 as against £740 this year and an actual expenditure last year of £664 The committee s estimate for Purdysburn Fever Hospital is £3200 compared with £2 [illegible] in 1931–32 and £2 803 11 in 1930–31 Payments in respect of maintenance of patients [illegible] and [illegible] receipts should produce £1 810 reducing the cost of the hospital to £30 220 Expenditure on the treatment of venereal diseases is calculated at £6 500 towards which there is a Government grant of £5 175 and £1 00 from county councils

Education of School Children

At a recent meeting in Belfast of the Northern Ireland branch of the New Education Fellowship Dr Olive Anderson said there were many matters about which parents and teachers ought to give personal instruction to children Children should never be coddled They should be allowed to run about a minimum of clothes and plenty of fresh air kept them fit A child s ailments should not be discussed in his presence nothing was more injurious Great harm was done by paying too much attention to the child and also by parents or teachers paying too little attention to their own motives and attitudes A child should never be allowed to shirk a duty because he did not want to do it It was for those in charge of the child to set an example Referring to the problem of sex Dr Anderson stated that children should be told the truth individually It was almost criminal to allow a boy or girl to grow up without sex knowledge as lack of it caused a great deal of physical and mental ill health

England and Wales

Public Health in Newcastle upon Tyne

In his last annual report Dr Harold Kerr medical officer of health for the city and county of Newcastle upon Tyne refers to the satisfactory slight decrease in the maternal mortality rate in the city during 1930 (5 36 as compared with 5 85 in the preceding year) The infant death rate also established a new record at 74 per 1 000 births being 11 per 1 000 less than in the previous year there were fewer stillbirths and premature births Three new maternity and child welfare centres were opened during the year and have supplied a great need in the new housing areas A training course was established for additional members of the staff of these centres and the growth of this work was reflected in the improved infantile mortality rate There was a substantial increase in the attendance at the centres and especially of expectant mothers and pre school children The death rate from pulmonary tuberculosis was 1 05 which is equal to the lowest recorded hitherto and for the non pulmonary form 0 24 per 1 000 which has not previously been equalled The new sanatorium ward block in the City Hospital for Infectious Diseases was continuously occupied by tuberculous patients but proved inadequate to meet the conditions resulting from the transfer of Poor Law hospital cases and one of the temporary wards belonging to the fever section of the hospital had to be set aside for tuberculosis Dr Kerr points the necessity of installing an x ray plant at the tuberculosis dispensary since only 60 per cent of the dispensary patients who require radiographic examination receive it at present In part explanation of the delay in notifying tuberculosis the prevalence of this disease in the North East of England is stated In view of the financial difficulties of the hospital the Royal Victoria Infirmary had undertaken the establishment of a contributory fund for Northumberland and Durham under which regular payments of small sums [illegible] contributors to Hospital treatment for themselves and their families

Society for Relief of Widows and Orphans of Medical Men

A quarterly court of the directors of this society was held on January 6th with the president Mr V Warren Low in the chair A vote of condolence on the death of Sir William Bennett senior vice president of the society was carried The death of one of the widows was reported she had been in receipt of grants since 1897 and had received a total sum of £3 100 Her late husband was elected a member in 1856 and died in 1897 having paid in subscriptions £52 10s A sum of £1,695 was voted for the half yearly grants, to be distributed among the forty nine widows and six orphans in receipt of grants and a further sum of £112 10s as special grants to five orphans who were over the age of 16 at which age the ordinary grants cease to enable them to continue their education and help them in studying for a profession The expenses of the past quarter were £88 2s 6d It was decided that at the next court the best means of making the society better known should be thoroughly discussed as many medical men are apparently unaware of its existence Membership is open to any registered medical man who at the time of his election is resident within a twenty mile radius of Charing Cross The annual subscription ranges from £2 2s to £4 4s according to the age of the member at the time of his election Relief is granted only to the widows and orphans of deceased members The secretary will forward particulars of membership to any medical man desirous of joining The offices of the society are at 11 Chandos Street Cavendish Square W 1 and the secretary attends there every Wednesday and Friday between 3 and 4 p m

King Edward's Hospital Fund

At a meeting of the General Council of King Edward's Hospital Fund for London held at 7 Walbrook, on January 5th the order of appointment signed by the Prince of Wales as president of the members of the General Council members of committee and officers for the year 1932 was read It was reported that His Royal Highness had appointed the following new members of the Hospital Economy Committee the Hon Margaret Bigge Dr Hugh Thursfield and Commander Alfred Williams A resolution was adopted expressing regret at the death of Sir William Bennett who had done good service to the King's Fund and the hospitals during many years On the motion of Lord Ebbisham seconded by Dr H Morley Fletcher the resolutions providing for the work of the Fund for 1932 which were approved at the meeting of the President and General Council held on December 11th 1931 were formally adopted including the terms of reference to the special committee appointed to inquire into the out patient question

London Ambulance Service

In December 1930 a circular was issued by the London County Council describing the facilities afforded by the London ambulance service and giving instructions for obtaining its help Under the conditions set out in this leaflet ambulances are supplied by the Council free of cost for the conveyance of patients to hospitals or private residences and to the council's hospitals for infectious diseases Ambulances and ambulance omnibuses are also provided at fixed charges for private patients within and beyond the administrative County of London Medical practitioners in London who desire to have a copy of the circular should apply to the medical officer of health for the metropolitan borough in which they practise Last month a new ambulance station was opened at Mount Nod Road, Streatham, supplementing the day and night South Western (Accident) Station in Landor Road Stockwell

Correspondence

NOTIFICATION OF INDUSTRIAL DISEASES

Statutory Requirements

SIR,—Many medical men are, I am afraid, unaware of their statutory obligation to notify certain industrial diseases I may quote two recent examples in regard to toxic jaundice one a series of cases due to tetrachlorethane, and the other a series due to arseniuretted hydrogen Only one of the cases was notified by a medical practitioner In the series due to arseniuretted hydrogen notification of the earliest case would have led to the adoption of measures which might it is anticipated have prevented the occurrence of subsequent cases including two deaths This serious result alone seems to be ample justification for asking you to allow me to draw the attention of the profession to the very important statutory requirement of notification of industrial poisoning under the Factory and Workshop Acts 1901–20 and Lead Paint (Protection against Poisoning) Act 1926

Every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from any of the following—

- Lead poisoning
- Phosphorus poisoning
- Arsenical poisoning
- Mercurial poisoning
- Carbon bisulphide poisoning
- Aniline poisoning
- Chromic benzene poisoning
- Anthrax
- Toxic jaundice
- Epitheliomatous ulceration or
- Chrome ulceration

} contracted in any factory or workshop

is required by Section 73 of the Factory and Workshop Act 1901, under penalty to notify the case forthwith to the Chief Inspector of Factories, Home Office London S W 1 and by Section 3 of the Lead Paint (Protection against Poisoning) Act 1926 he is also required to notify lead poisoning contracted by any person employed in, or in connexion with the painting of any building whether or not that building is a factory or workshop unless it has already been so notified and he is entitled to a fee of 2s 6d for so doing Forms for notification will be supplied on application to the Chief Inspector of Factories Home Office, S W 1 —I am etc,

JOHN C BRIDGE
H M Senior Medical Inspector of Factories

January 11th

MEDICAL TREATMENT OF GASTRIC ULCER

SIR,—Lord Moynihan's lecture on the prognosis of gastric ulcer published in your issue of January 2nd, is interesting to physicians owing to the light it throws upon the failure of medical treatment as commonly undertaken

Medical treatment fails from three chief causes (1) relief of pain is taken to mean cure of the lesion, (2) sufficient stress is not placed upon the necessity for complete rest during treatment (3) the improper but unavoidable treatment of patients with gastric ulcer as out patients inculcates into students and house physicians the idea that such a measure is adequate The widespread nature of such a belief was revealed to me during a recent M B examination when students from several London schools replied that out-patient alkali treatment was adequate

Rest is an essential in the treatment of any lesion which heals with difficulty, and this can be obtained for the

stomach in a variety of ways. The routine followed by myself is as follows:

1. Rest in bed until the ulcer has healed, the criterion of healing being three negative occult blood tests upon successive feeds and the recovery on examination of both deformity and local tenderness.
2. Half a drachm of a standard alkali powder after each feed.
3. Strict Lenhartz diet. If healing is delayed a second course is given, starting from the third day of the diet.
4. Belladonna is prescribed being given in full pharmacological dose—that is just below the level of tolerance. The tolerated dose often is high as [illegible] drops per diem of tincture belladonnæ.
5. Olive oil 3ss nocte. This both inhibits gastric secretion during the night and produces some laxative effect.

The total duration of such a course may be as long as ten weeks. This routine or one of equal severity is necessary before any group of cases can be regarded as having undergone adequate medical treatment, and no statistical information as to the value of medical treatment of gastric ulcer can be trustworthy unless based upon similarly treated groups of cases. Relief of pain and apparent healing can be obtained by less stringent means, but relapse is common.

A point of great importance arises if the above premisses be granted—namely, that treatment on these lines would soon result in the overfilling of the beds of general hospitals with cases of chronic gastric ulcer. It would therefore seem that the disease will not receive thorough treatment until there is available a large hospital whose whole activities are directed to this form of therapy upon a mass scale. To such an institution the surplus cases could be referred from general hospitals. Only in this way will the out-patient departments be freed from the reproach of inadequately treating patients with chronic gastric ulcer who are awaiting admission. At present their only means of obtaining adequate therapy are by producing a haematemesis, by suffering a perforation, or by prolonging an interminable existence dependent upon the doubtful vagaries of a long waiting list.—I am, etc.,

London, W.1, Jan. 5th. GEOFFREY BOURNE.

COLPORRHAPHY FOR PROLAPSE

SIR,—I was much interested in the article in the *Journal* of December 26th, 1931, on displacements of the uterus and the pelvic floor by Dr. S. Gordon Luker, and so pleased to find that he advises the operation of colporrhaphy as the treatment for prolapse of the uterus. Thanks to the pioneer work of my old chief, Professor A. Donald, this operation was firmly established in Manchester for the treatment of prolapse when I first entered the ranks of gynæcology twenty-seven years ago, and so good are its results that I have never employed any other.

I am sorry to see that Dr. Luker flirts with the idea of combining a ventral suspension operation with the colporrhaphy, and I am especially sorry to see the reason he gives for this combination. He considers it to be unnecessary in old people because the vagina can be made much tighter in the operation than in young or married women, and apparently he looks upon the tightness of the vagina as a factor in the cure of the condition. This I think is quite wrong, and whether the patient is old or young we do not consider an over-tight vagina to be an indication of manipulation on the part of the operator, and our endeavour is always to cure the prolapse by first suturing the deep structures without removal of an excessive amount of vaginal tissue. The only type of case in which ventral fixation might be necessary is the elderly virgin—the only other type being one in which there is advanced destruction of the pelvic floor. Even in this type of patient there is usually sufficient muscular tissue to make a good pelvic floor. [illegible] years of gynæcological practice [illegible] found it necessary to combine the operation with [illegible] than three or four occasions.

My chief reason for writing is to call attention to Dr. Gordon Luker's statement that it is [illegible] for a woman to have another child after [illegible] prolapse has been done as the [illegible] will be lessened and prolapse recur. There is a chance of recurrence whenever a woman has a child after colporrhaphy, just as there is with every parturient; and I do not think the percentage of recurrences is greater in these cases than that of the original prolapse in the other. I recently published in the *Proceedings of the Obstetrical Section of the Royal Society of Medicine* (Jan. 1932) quoted eighteen patients who went through labour after colporrhaphy was performed, and in only five (27.8 per cent.) was there any degree of recurrence.

Quite naturally we prefer to operate upon patients who have completed their families, but in the case of a young woman who has considerable discomfort from a prolapsed uterus after one child it is not necessary to consider [illegible] necessary treatment for [illegible] long period of years or to consider sterilization along with the operation of colporrhaphy. Colporrhaphy is an operation with a very low risk, and such a patient can have a colporrhaphy performed and be made quite comfortable with the knowledge that any further labour has no more risk of producing a recurrence than had the original labour, and that the difficulty of the labour itself is not increased.—I am, etc.,

W. FLETCHER SHAW, M.D., F.R.C.O.G.

Manchester, Jan. 6th.

THE PROPHYLAXIS OF TUBERCULOSIS

SIR,—Dr. Middleton Martin's interesting collection of salient facts (published in your issue of January 9th) seem to me to lead to other conclusions than the author draws from them. His final sentence reads: "Our aim should be to reduce the infection to the minimal protective dose—for example, by the commercial pasteurization of milk," etc.

In an earlier paragraph (7) he says: "7 per cent. of the samples [of cow's milk] are reported to be infected with the bovine form of the bacillus," and later: "it is more or less generally accepted that immunity more or less complete is afforded by early infection." If an early bovine infection safeguards against adult developments, why neutralize so benign a possibility by pasteurizing milk? Another conclusion [illegible] states: "Tuberculosis schemes do not appear to have had appreciable results in reducing the amount of tuberculous illness." Surely if that is true, undue expenditure going on all over the country by municipal, county service both residential and domiciliary, except [illegible] as he claims have an indirect effect to stimulate health living among the general population.

Present economic stringency calls for careful scrutiny of all public spending, and the fact that tuberculosis has a particularly harsh distribution of public funds allotted to it for certain definite purposes should call any modification of these reasons to be considered with special care. The arguments set forth in Dr. Martin's paper might reasonably suggest certain curtailments or alterations and conservations of the [illegible]. If, for instance, we can believe (*a*) that the fall of the death rate from tuberculosis is likely to proceed independently of our campaigning, (*b*) that the factor of direct personal infection has been unduly emphasized, and (*c*) that the commercial pasteurization of milk would lessen the toll of childhood tuberculosis, there surely a new orientation of outlook is definitely called for.

How may we best reduce infection to the protective minimal dose ? In discovering the right answer to this question much of our present work may be found of doubtful value but the 'problem of tuberculosis' is still a sufficient burden to demand a revised investigation in the light of fresh knowledge and accumulated experience —I am etc ,

CATARRHAL INFECTION AND FORMALIN VAPOUR

SIR —The memorandum by Dr Wells on the above subject in the *Journal* of January 9th, recalls to my mind an instructive and perhaps interesting incident which occurred during the war but it is now so many years ago that I cannot pledge myself to more than the substantial accuracy of the facts I state

We were experiencing a sudden and severe epidemic of influenza in the camp at Wimbledon to which I was senior medical officer and the men were disabled by the score—this of course threw a great strain on my medical officers and we decided to disinfect with formalin Regarding the matter as urgent I got into a light ambulance next morning and was driven to—let us say—Depot A ' where I indented for one gallon of formaldehyde They were sorry they had run out of it no doubt if I would go to Depot B I would be supplied but it would be wise to ask for three gallons The courteous officers at Depot B were in the same position , but I would certainly get it at Depot C provided I did not ask for less than ten gallons At Depot C I was told that it would be delivered that afternoon I got back to camp feeling very ill with influenza unable to eat any luncheon and only fit for bed to which I betook myself About 3 o clock my sergeant woke me to say that a lorry had delivered twenty gallons of formaldehyde what was he to do? My only reply was Disinfect and be —— , and here I fell asleep The next minute as it seemed to me I wakened coughing spluttering and feeling half suffocated Jumping out of bed I discovered my sergeant in much the same condition as myself vigorously scrubbing the floor with a stable broom which he was dipping in a pail of pure formaldehyde Postponing for the moment any observations I wished to make I rushed out for the fresh air when soon to my astonishment I began to feel much better I dined in mess that night I was well next day and taking the hint less heroic but equally effective from the sergeant s method we cleared the camp of influenza in less than a week —I am etc

OXYGEN AND EVEREST

SIR —Mr Odell in a letter to *Nature* of December 19th 1931 re emphasized conclusions drawn from the Everest expeditions as to the value of oxygen breathing apparatus and upheld the importance of acclimatization He stated that acclimatization at 27 000 to 28 000 feet should be aimed at and then oxygen used for the last 1 000 feet of ascent As it takes weeks for the party to reach 27 000 feet experiments in pressure chambers conducted on normal men for a few hours duration are of no significance We know however that natives do not go and live in the summer months above 18 000 feet and the question arises whether it is the altitude or the extent of the pastures which sets this limit

It was on account of this that Dr Argyll Campbell carried out many experiments with animals while I was in charge of the Department of Applied Physiology at the National Institute for Medical Research He used monkeys, cats rabbits, guinea pigs rats and mice enclosing these animals almost continuously in chambers for many weeks either the oxygen partial pressure or the barometric pressure being lowered gradually to resemble the conditions on the mountains In the latter case use was made of a chamber at Messrs Siebe Gorman s works His results have been published, and clearly show that at 20 000 to 29 000 feet the oxygen tension in the tissues is not kept at normal, but is markedly subnormal further, there result pathological changes particularly in the heart liver and brain Also he found that breathing oxygen at normal pressure for one hour daily did not help these animals materially

Thus in the so called acclimatization at these great altitudes the members of the expeditions will be deteriorating continuously that they did so in the past expeditions is proved, by the facts both that climbing became most difficult and that they all lost weight and appetite The climbers who persevered at 28 000 feet or above all came to grief

Another expedition of the same type is likely to end similarly unless other precautions are taken Dr Campbell found that out of more than a hundred healthy animals only about ten could tolerate the low oxygen partial pressure which pertains at 29 000 feet for any length of time A few animals survived for eight days—a record—under this pressure and recovered their health again when put under normal conditions
